This application note describes the Peripheral Reflex System (PRS) features and how these can be used to improve the system’s energy performance and reduce MCU workload and latency.

Some examples are presented and described in detail.

For simplicity, EFM32 Wonder Gecko, Gecko, Giant Gecko, Leopard Gecko, Tiny Gecko, Zero Gecko, and Happy Gecko are a part of the EFM32 Gecko Series 0.

EZR32 Wonder Gecko, Leopard Gecko, and Happy Gecko are a part of the EZR32 Wireless MCU Series 0.

EFM32 Pearl Gecko and Jade Gecko (and future devices) are a part of the EFM32 Gecko Series 1.

EFR32 Blue Gecko, Flex Gecko, and Mighty Gecko are a part of the EFR32 Wireless Gecko Series 1.

**KEY POINTS**

- This document discusses PRS producers and consumers.
- Asynchronous mode PRS for EM2/3 operation.
- The enhanced PRS supports configurable logic.
- This application note includes:
  - This PDF document
  - Source files
  - Example C-code
  - Multiple IDE projects
1. Peripheral Reflex System

1.1 Introduction

The Peripheral Reflex System (PRS) system is a network that lets the different peripheral modules communicate directly with each other without involving the MCU. Peripheral modules that send out reflex signals are called producers. The PRS module routes these reflex signals to consumer peripherals that apply actions depending on the reflex signals received. The format for the reflex signals is not given, but edge triggers and other functionality can be applied by PRS.

1.2 Overview

An overview of one channel and how 4 different peripherals can be connected PRS is given in Figure 1.1 PRS Overview on page 1. The PRS module contains certain interconnect channels (see the device reference manual for the available PRS channels), and each of these can select between all the output reflex signals offered by the producers. The consumers can then choose which PRS channel to listen to and perform actions based on the reflex signals routed through that channel. The reflex signals can be both pulse signals and level signals. Synchronous PRS pulses are one HFPERCLK or HFBUSCLK cycle long, and can either be sent out by a producer, for example ADC conversion complete, or be generated from the edge detector in the PRS channel. Level signals can have an arbitrary waveform, but will be synchronized with the HFPERCLK.

Figure 1.1. PRS Overview

The example in Figure 1.1 PRS Overview on page 1 shows four peripherals connected to two PRS channels. On one channel is TIMER0 and ADC0 and the ACMP and TIMER1 are connected to a second channel. An overflow from TIMER0 can start an ADC single conversion, and an ACMP output can be used as input for a Compare/ Capture channel on TIMER1.
2. General Operation

2.1 Asynchronous Mode

Reflex channels can operate in two modes: synchronous or asynchronous. In synchronous mode, reflex signals are clocked on the HFPERCLK or HFBUSCLK (available in EFM32 Gecko Series 1 and EFR32 Wireless Gecko Series 1 devices) and can be used by any reflex consumer. However, this will not work in Energy Mode 2 (EM2) or Energy Mode 3 (EM3), since the HFPERCLK or HFBUSCLK will be turned off.

Asynchronous reflex channels are not clocked on HFPERCLK or HFBUSCLK and can be used even in Energy Mode 2 (EM2) or Energy Mode 3 (EM3). However, the asynchronous mode can only be used by a subset of the reflex consumers marked with Async Support in Table 2.3 Reflex Consumers on page 6. Peripherals that can produce asynchronous reflexes are marked with Async Support in Table 2.2 Reflex Producers on page 4.

To use these reflex signals asynchronously, set the ASYNC bitfield in the PRS_CHx_CTRL register for the PRS channel selecting the reflex signal (see 4.6 Asynchronous GPIO PRS Triggered PCNT in EM2 and 5.4 Asynchronous GPIO PRS Triggered PCNT in EM3).

Note:
1. Asynchronous mode is not available in the EFM32 Gecko (EFM32G) device.
2. If a reflex channel with ASYNC set is used in a consumer not supporting asynchronous reflexes, the behavior is undefined.

2.2 Channel Functions

Different functions can be applied to a reflex signal within the PRS module. Each channel includes an edge detector to enable generation of pulse signals from level signals.

Edge detection can be applied to a PRS signal using the EDSEL bitfield in the PRS_CHx_CTRL register. When edge detection is enabled, changes in the PRS input will result in a pulse on the PRS channel.

In EFM32 Gecko Series 1 and EFR32 Wireless Gecko Series 1 devices:

• Signals on the PRS input also have to be at least one HFBUSCLK period wide in order to be detected properly. This applies to all cases when asynchronous mode is not used in the PRS.
• There are two options for communication between peripherals on different prescaled clocks, for example between peripherals on HFBUSCLK and HFPERCLK:
  • For level signals, no action is needed, but software must make sure that the level signals are held long enough for the destination domain to detect them.
  • For pulse signals, edge detection and stretch (EDSEL and STRETCH bitfields in the PRS_CHx_CTRL register) should be enabled. When edge detection and stretch are enabled on a PRS source, the output on the PRS channel is held long enough for the destination domain to detect the pulse. This also works if there are multiple destination domains running at different frequencies.

The PRS channels can also be manually triggered by writing to the PRS_SWPULSE or PRS_SWLEVEL registers (see 4.4 Software Generated PRS Pulse Triggers DAC Conversion).

PRS_SWLEVEL is a programmable level for each channel and holds the value it is programmed to. The PRS_SWPULSE register will cause the PRS channel to output a one-HFPERCLK or one-HFBUSCLK cycle high pulse if the corresponding channel bit is set to 1.

The SWLEVEL and SWPULSE signals are then XOR'ed with the selected input from the producers to form the output signal sent to the consumers listening to the channel. For example, when SWLEVEL is set, if a producer produces a signal of 1, this will cause a channel output of 0. This is illustrated in Figure 1.1 PRS Overview on page 1.

The emlib functions

• void PRS_SourceSignalSet(unsigned int ch, uint32_t source, uint32_t signal, PRS_Edge_TypeDef edge)
• void RS_SourceAsyncSignalSet(unsigned int ch, uint32_t source, uint32_t signal)

can be used to easily configure the PRS channels.

By specifying the PRS channel, producing peripheral, signal from the peripheral, and edge for pulse generation (synchronous mode), the function configures the PRS accordingly.

Note: The edge detector controlled by the EDSEL bitfield in the PRS_CHx_CTRL register should only be used when working with synchronous reflexes, that is, the ASYNC bitfield in the PRS_CHx_CTRL register is cleared.
2.3 Route PRS Channel to GPIO Pin

It is possible to route a PRS channel to a GPIO pin for debugging or use it as an enable signal.

Table 2.1. Route PRS Channel to GPIO pin

</tr>
</tbody>
</table>

**Note:** This feature is not available in the EFM32 Gecko (EFM32G) device.
2.4 Producers

Each PRS channel can choose between signals from several producers, which is configured in the SOURCESEL bitfield in the PRS_CHx_CTRL register. Each producer outputs a signal which can be selected by setting the SIGSEL bitfield in the PRS_CHx_CTRL register. Setting the SOURCESEL bitfield to 0 (off) leads to a constant zero output from the input mux. An overview of the available producers is given in the table below.

**Note:** Not all modules and reflex outputs are available on a given device. Refer to the device reference manual and data sheet for details.

**Note:**
1. The Async Support for ADC is not available in EFM32 Gecko Series 0 and EZR32 Series 0 devices.
2. USB PRS outputs must be synchronized in the PRS when used, that is, it is an asynchronous PRS output. The USB PRS outputs go to 0 in Energy Mode 2 (EM2) or Energy Mode 3 (EM3).
2.5 Consumers

Consumer peripherals (listed in the table below) can be set to listen to a PRS channel and perform an action based on the signal received on that channel. Most consumers expect a pulse input, while some can handle level inputs as well.

Note: Not all modules and reflex inputs are available on a given device. Refer to the device reference manual and data sheet for details.

**Note:**
1. The Async Support for ADC is not available in EFM32 Gecko Series 0 and EZR32 Series 0 devices.
3. Advanced Features

These advanced features are not available in EFM32 Gecko Series 0 and EZR32 Series 0 devices.

3.1 Configurable PRS Logic

Each PRS channel has three logic functions that can be used by themselves or in combination. The selected PRS source can be AND’ed with the next PRS channel output, OR’ed with the previous PRS channel output, and inverted. The order of the functions is important. If OR and AND are enabled at the same time, AND is applied first, and then OR.

In addition to the logic functions that can combine a PRS channel with one of its neighbors, a PRS channel can also select any other PRS channel as the input. This can allow relatively complex logic functions to be created (see 5.6 Configurable PRS Logic).

3.2 Event on PRS

The PRS can be used to send events to the MCU. This is very useful in combination with the Wait For Event (WFE) instruction. A single PRS channel can be selected for this using the SEVONPRSSEL bitfield in the PRS_CTRL register, and the feature is enabled by setting the SEVONPRS bitfield in the same register (see 5.5 Event on PRS).

3.3 DMA Request on PRS

Up to two independent DMA requests (PRSREQ0 and PRSREQ1) can be generated by the PRS.

The PRS signals triggering the DMA requests are selected with the SOURCESEL (= 0x1 for PRS) and SIGNAL (= 0x0 for PRSREQ0 or = 0x1 for PRSREQ1) bitfields in the LDMA_CHx_REQSEL register.

The PRS channels for DMA requests are configured in the PRS_DMAREQ0 and PRS_DMAREQ1 registers. See AN1029: Linked Direct Memory Access Controller (LDMA) for more information. Application notes can be found on the Silicon Labs website at [www.silabs.com/32bit-appnotes](http://www.silabs.com/32bit-appnotes) or in Simplicity Studio (http://www.silabs.com/simplicity).
4. Software Examples for EFM32 Gecko Series 0

The software examples below are run on the EFM32 Gecko (project prs_example_gecko or STKXXX_prs_example), Tiny Gecko (project prs_example_tg or STK3300_prs_example), and Giant Gecko Starter Kits (project prs_example_gg or STK3700_prs_example), with common source file main_prs_example.c.

The example is selected by the menu displayed on the segment LCD, push button PB0 is used to browse the menu, and push button PB1 is used to execute the selected menu item. Press push button PB0 to exit if the selected menu item is running.
4.1 TIMER Triggered ADC Conversion

This example shows how to set up ADC0 to start a single conversion every time that TIMER0 overflows. TIMER0 sends a one HFPERCLK cycle high pulse through the PRS on each overflow and the ADC does a single conversion which is displayed on the LCD.

The figure below shows a one HFPERCLK cycle pulse sent from TIMER0 to the ADC0 on an overflow. The signal triggers a single ADC conversion. The ADC consumes pulse signals which is the same signal produced by the TIMER. In this case, there is no edge detection needed, and the PRS leaves the incoming signal unchanged.

The ADC is configured with 12-bit resolution and VDD as both reference and input. When the ADC finishes the conversion, it generates a single conversion complete interrupt. The MCU will then fetch the result from the ADC0_SINGLEDATA register and display it on the LCD. The DMA can also be used to fetch the conversion result, and that is covered by AN0021 Analog to Digital Converter (ADC).

The function `void prsTimerAdc (void)` in source file `prs_timer_adc.c` implements this example.

Press the push button PB0 to select the [ADC].

Press push button PB1 to start TIMER trigger. The TIMER triggered (approximately every one second) ADC converted voltage, for example 3.288 V for VDD, will display on the segment LCD as shown below.
4.2 Pulse Width Measurement with ACMP and TIMER

This example shows how to measure the pulse width or period of an arbitrary waveform. The analog comparator (ACMP) is used to send a level signal through the PRS. TIMER0 consumes both pulse and level signals, so the PRS leaves the incoming signal unchanged. On TIMER0, the PRS signal is used as input for Compare/Capture channel 0 (CC0). TIMER0 starts counting on a rising edge and captures the counter value on a falling edge. The figure below shows the level output from the ACMP sent through the PRS to the TIMER which measures the positive pulse width using the capture feature.

![Diagram of ACMP and TIMER connections](image)

Figure 4.2. ACMP Level Output used as PRS Signal for TIMER0 CC0 channel input

To trigger the pulse width measurement, pin PC4 must be connected to VMCU to generate a high level that will trigger the ACMP and start the TIMER. When the connection is released, the output of the ACMP will be low again, and the TIMER captures the counter value and displays the positive pulse width in second on the LCD.

The function `void prsAcmpCapture (void)` in source file `prs_pulse_width_channel_scan.c` implements this example.

Press the push button PB0 to select the [PUL].

PUL

Press push button PB1 to start the pulse width measurement. The positive pulse width, for example 0.578 s, will display on the segment LCD as shown below when rising then falling edges are detected on PC4 (pin 3 of EXP header on EFM32 Gecko and Tiny Gecko Starter Kit, pin 7 of EXP header on Giant Gecko Starter Kit).
4.3 GPIO Triggered USART Transmission

This example shows how to use an external signal coming through the GPIO to enable the USART transmitter.

The figure below shows a falling edge from a GPIO pin sent on the producer side through the PRS edge detector to create a one HFPERCLK cycle pulse on the consumer side. The GPIO produces level signals which are not consumed by the USART, so the edge detector must be used to generate a pulse signal on a GPIO falling edge transition. The clock pulse enables the USART TX and transmits the data that was placed in the TX buffer.

![Diagram of GPIO Triggered USART Transmission](image_url)

**Figure 4.3. USART TX enabled by GPIO signal using the PRS**

The function `void prsGpioUsart(void)` in source file `prs_gpio_usart.c` implements this example.

Press the push button PB0 to select [UART].

UART

Press push button PB1 to wait GPIO trigger for USART transmission. Every press on PB1 will trigger a single character (cycle from character 0 to 9) USART transmission (115200 baud rate, no parity and one stop bit) on PD0 (pin 4 of EXP header on Starter Kit).
4.4 Software Generated PRS Pulse Triggers DAC Conversion

This example shows how to generate a PRS pulse by software. The PRS pulse will trigger a DAC conversion which outputs a 0.5 V signal on pin PB12 (pin 13 of EXP header on Starter Kit). It is possible to generate both pulse and level signals by software. In this case, a pulse signal is generated because it is the type of signal consumed by the DAC. DAC conversions can also be started by software in the DAC itself. This example only shows how this can be done through the PRS as well.

The figure below shows a one HFPERCLK cycle pulse triggered from software. Pulse and level signals can be generated by software by writing directly to the PRS_SWPULSE and PRS_SWLEVEL registers respectively. They can also be generated using functions from the emlib.

- `void PRS_PulseTrigger(uint32_t channels)` generates pulse signals
- `void PRS_LevelSet(uint32_t level, uint32_t mask)` generates level signals

![Figure 4.4. Software Triggered PRS Signal.](image)

The function `void prsSwDac (void)` in source file `prs_soft_dac.c` implements this example.

Press the push button PB0 to select [DAC].

```
DAC
```

Press push button PB1 to start the software trigger and the DAC voltage (0.5 V) will display on the segment LCD as shown below.

```
0500
DAC RUN
```
4.5 Monitoring of PRS Signals

The PRS channels can be monitored using peripherals that consume PRS signals. One example is using a TIMER to make a capture when there is activity on the PRS channel it is connected to.

The Compare/Capture channel 0 (CC0) on TIMER0 is used to capture a falling edge. When a capture is triggered, the user knows that there was activity on the selected PRS channel.

This example will wait on Energy Mode 1 (EM1) for activity in the PRS channel (TIMER0 capture interrupt). When such activity occurs, it writes the PRS trigger count on the LCD. To generate activity on this line, the user must connect PC4 (pin 3 of EXP header on EFM32 Gecko and Tiny Gecko Starter Kit, pin 7 of EXP header on Giant Gecko Starter Kit) to VMCU to generate a rising edge transition on the PRS channel using the analog comparator (ACMP).

This example is useful for EFM32 Gecko (EFM32G) devices that cannot route a PRS channel to a GPIO pin for monitoring or debugging.

The function `void prsMonitor (void)` in source file `prs_pulse_width_channel_scan.c` implements this example.

Press the push button PB0 to select [MON].

Press push button PB1 to start the monitor process and the PRS trigger count will display on the segment LCD as shown below.

0003
MON RUN
4.6 Asynchronous GPIO PRS Triggered PCNT in EM2

This example shows how to use an external signal coming through the GPIO to clock the pulse counter (PCNT). Asynchronous mode PRS is used since both GPIO and PCNT can support this feature.

The figure below shows the level output from the GPIO sent through the asynchronous PRS to the PCNT which clocks the PCNT counter at a rising edge. The LFRCO is used for the LFA clock (LCD and PCNT) so this example can run in Energy Mode 2 (EM2) but not in Energy Mode 3 (EM3).

The function `void prsGpioPcnt (void)` in source file `prs_gpio_pcnt.c` implements this example.

**Note:** The EFM32 Gecko (EFM32G) device does not support asynchronous mode PRS, so this example is not available on the EFM32 Gecko STK.

Press the push button PB0 to select [PCNT].

PCNT

Press push button PB1 to trigger the PCNT counter and the counter value will display on the segment LCD as shown below.

```
0003
PCNTRUN
```
5. Software Examples for EFM32 Gecko Series 1

The software examples below are run on the EFM32 Pearl Gecko Starter Kit (SLSTK3401A_EFM32PG). These examples are grouped into one project (prs_example_pg or SLSTK3401A_prs_example) with source file main_prs_example.c.

The example is selected by the menu displayed on the Memory LCD, push button BTN1 is used to browse the menu, and push button BTN0 is used to execute the selected menu item. Press push button BTN1 to exit if the selected menu item is running.

5.1 TIMER Triggered ADC Conversion

Refer to 4.1 TIMER Triggered ADC Conversion for a detailed description of this example. The function void prsTimerAdc (void) in source file prs_timer_adc.c implements this example.

Press the push button BTN1 to select [Timer Triggered ADC Conversion].

```
Example 1
Timer Triggered
ADC Conversion

Press BTN1 to next
menu
Press BTN0 to start
```

Press push button BTN0 to start the TIMER trigger. The TIMER-triggered (approximately every one second) ADC-converted voltage will display on the Memory LCD as shown below.

```
Example 1
Timer Triggered
ADC Conversion

Trigger interval ~1s
AVDD: 3.2887V

Press BTN1 to exit
```

5.2 Pulse Width Measurement with ACMP and TIMER

Refer to 4.2 Pulse Width Measurement with ACMP and TIMER for a detailed description of this example. The function void prsAcmpCa pture (void) in source file prs_pulse_width_channel_scan.c implements this example.

Press the push button BTN1 to select [Pulse Width Measurement on PA4 with ACMP and TIMER].

```
Example 2
Pulse Width
Measurement on PA4
with ACMP and TIMER

Press BTN1 to next
menu
Press BTN0 to start
```

Press push button BTN0 to start the pulse width measurement. The pulse width will display on the Memory LCD as shown below when rising then falling edges are detected on PA4 (pin 7 of EXP header on Starter Kit).

```
Example 2
Pulse Width
Measurement on PA4
with ACMP and TIMER

Positive pulse width:
0.2399s

Press BTN1 to exit
```
5.3 GPIO Triggered USART Transmission

Refer to 4.3 GPIO Triggered USART Transmission for a detailed description of this example. The function `void prsGpioUsart (void)` in source file `prs_gpio_usart.c` implements this example.

Press the push button BTN1 to select [GPIO Triggered USART Transmission].

Example 3
GPIO Triggered USART Transmission
Press BTN1 to next menu
Press BTN0 to start

Press push button BTN0 to start GPIO triggers for USART transmission. Every press on BTN0 will trigger a single character (cycle from character 0 to 9) USART transmission (115200 baud rate, no parity and one stop bit) on PC7 (pin 6 of EXP header on Starter Kit).

Example 3
GPIO Triggered USART Transmission
Press BTN0 to trigger USART TX on PC7
Character: 1
Press BTN1 to exit

5.4 Asynchronous GPIO PRS Triggered PCNT in EM3

Refer to 4.6 Asynchronous GPIO PRS Triggered PCNT in EM2 for a detailed description of this example. The function `void prsGpioPcnt (void)` in source file `prs_gpio_pcnt.c` implements this example. The ULFRCO is used for the LFA clock (PCNT) so this example can run in Energy Mode 2 (EM2) and Energy Mode 3 (EM3).

Press the push button BTN1 to select [Asynchronous GPIO PRS Triggered PCNT in EM3].

Example 4
Asynchronous GPIO PRS Triggered PCNT in EM3
Press BTN1 to next menu
Press BTN0 to start

Press push button BTN0 to trigger the PCNT counter, and the counter value will display on the Memory LCD as shown below.

Example 4
Asynchronous GPIO PRS Triggered PCNT in EM3
Press BTN0 to trigger PCNT
PCNT CNT: 00003
Press BTN1 to exit
5.5 Event on PRS

This example demonstrates how to send event to the MCU through the PRS.

The TIMER0 is setup to trigger an event to the MCU periodically (approximately every one second), every time letting the MCU pass through a Wait For Event (WFE) instruction in its program.

This can help in performance critical sections where timing is known, and the goal is to wait for an event, then execute some code, then wait for an event, then execute some code and so on.

The function `void prsTimerWfe (void)` in source file `prs_timer_wfe.c` implements this example.

Press the push button BTN1 to select [Event on PRS - WFE in EM1].

Press push button BTN0 to start the TIMER trigger, and the wake up count will display on the Memory LCD as shown below.

5.6 Configurable PRS Logic

This example demonstrates how to use the configurable logic in PRS to reduce the current consumption in a thermistor application.

The target is to evaluate the ADC result (temperature) autonomously and only give the MCU an interrupt if the sample is outside or inside the given thresholds.

The functions `void rtccSetup (void)`, `void adcPrsLogic (void)`, `void adcSetup (void)`, and `void prsConfigLogic (void)` in source file `prs_rtcc_logic.c` implement this example.
5.6.1 Design Concept

Power gating is critical in this scenario, since the current consumption of the thermistor (~30 to 60 μA) becomes dominant in sleep mode (~2 μA) unless the MCU makes sure the thermistor is powered only when it is being sampled.

This can be achieved by routing the RTCC signal (RTCC Event) to a GPIO pin to drive the thermistor. This scenario is shown in Figure 5.1 ADC Sample Triggered by RTCC Event through PRS on page 19.

![Figure 5.1. ADC Sample Triggered by RTCC Event through PRS](image)

The RTCC Event pulse width is ~30.5 μs if based on a 32768 Hz clock (LFRCO or LFXO) and 1 ms if based on a 1 kHz clock (ULFRCO). As the figure above shows, the RTCC Event is longer than the ADC takes to warm up and sample the thermistor, so the RTCC Event keeps the thermistor on longer than necessary.

The thermistor on time can be further reduced by using combinational logic. For example, the ADC produces a short PRS output whenever it is done. Using the RTCC event PRS signal and the ADC conversion done PRS pulse, it is possible to create a signal that goes high on the RTC trigger and low when the ADC is complete. This signal can automatically enable the thermistor in the system.

The conceptual circuit for this example, which starts external sensor excitation on RTCC trigger and ends excitation when ADC sample has been taken, is shown in Figure 5.2 Conceptual Circuit on page 19. The truth table of this circuit is shown in Table 5.1 Truth Table of Conceptual Circuit on page 20.

![Figure 5.2. Conceptual Circuit](image)

</tr>
</tbody>
</table>

Initially, the SR latch output /Q is high and Enable Sensor is low because the RTCC_Event output and the ADC_Done output are low. Whenever the RTCC_Event now goes high, the external sensor is enabled, and the ADC starts taking a sample. Once the ADC is done, the ADC_Done signal goes high, setting the SR latch output /Q low, which forces the external sensor off. When the RTCC event signal goes low again, the SR latch is reset, making the system ready for the next event.
5.6.2 Design Implementation

The circuit shown in Figure 5.2 Conceptual Circuit on page 19 can easily be implemented on an EFM32 Pearl Gecko (EFM32PG) using the Peripheral Reflex System (PRS), which contains logic elements that can be connected together in various ways.

The Figure 5.3 PRS Logic Implementation for Excitation of External Sensor on page 21 shows what this implementation would look like using six of the available PRS channels. The Table 5.2 PRS Logic Configuration for Excitation of External Sensor on page 22 shows how the six PRS channels are configured to enable this functionality.

The configuration of Table 5.2 PRS Logic Configuration for Excitation of External Sensor on page 22 can be realized by C source code as shown below.

```c
CMU_ClockEnable(cmuClock_PRS, true);
/* Use ADC SINGLE as an ASYNC PRS producer on CH0 */
PRS_SourceAsyncSignalSet(0, PRS_CH_CTRL_SOURCESEL_ADC0, PRS_CH_CTRL_SIGSEL_ADC0SINGLE);

/* CH3 OR CH0 then INV on CH1 */
PRS_SourceAsyncSignalSet(1, PRS_CH_CTRL_SOURCESEL_PRSL, PRS_CH_CTRL_SIGSEL_PRSCH3);
PRS->CH[1].CTRL |= PRS_CH_CTRL_ORPREV | PRS_CH_CTRL_INV;

/* Invert RTCC trigger on CH2 */
PRS_SourceAsyncSignalSet(2, PRS_CH_CTRL_SOURCESEL_RTCC, PRS_CH_CTRL_SIGSEL_RTCCCV1);
PRS->CH[2].CTRL |= PRS_CH_CTRL_INV;

/* CH1 OR CH2 then INV on CH3 */
PRS_SourceAsyncSignalSet(3, PRS_CH_CTRL_SOURCESEL_PRSL, PRS_CH_CTRL_SIGSEL_PRSCH1);
PRS->CH[3].CTRL |= PRS_CH_CTRL_ORPREV | PRS_CH_CTRL_INV;

/* CH1 AND CH5 on CH4 */
PRS_SourceAsyncSignalSet(4, PRS_CH_CTRL_SOURCESEL_PRSL, PRS_CH_CTRL_SIGSEL_PRSCH1);
PRS->CH[4].CTRL |= PRS_CH_CTRL_ANDNEXT;

/* Use RTCC as an ASYNC PRS producer on CH5 */
PRS_SourceAsyncSignalSet(5, PRS_CH_CTRL_SOURCESEL_RTCC, PRS_CH_CTRL_SIGSEL_RTCCCVC1);
```
5.6.3 Test Results

This example uses the configurable PRS logic to trigger the ADC single conversion at 100 Hz. The EFM32 Pearl Gecko stays in Energy Mode 3 (EM3) and wakes up with the ADC SINGLECMP interrupt.

The clock configurations for this example are listed below.

- Core clock — 16 MHz HFRCO
- ADC conversion clock — 13 MHz AUXHFRCO in ASYNC mode
- RTCC — Use 1 kHz ULFRCO as clock source for EM3 operation

The ADC configurations for this example are listed below.

- PRS enable — Trigger from PRS channel 4
- Reference — AVDD
- Input — PA0 (pin 12 of EXP header on EFM32PG Starter Kit)
- FIFO overflow action — FIFO overwrites old data when full
- ADC acquisition time — One ADC conversion clock cycle
- ADC conversion resolution — 12 bit
- ADC bias programming — Set GPBIASACC bitfield in the ADCn_BIASPROG register to LOWACC
- ADC clock mode — ASYNC and use AUXHFRCO as clock source for EM3 operation
- ADC interrupt — Single result compare matched (SINGLECMP)

The ADC compare thresholds below are used in this example.

- ADC ADGT — 3724 (~3V for AVDD = 3.3 V)
- ADC ADLT — 620 (~0.5V for AVDD = 3.3 V)

The ADC compare matched interrupt will be triggered when PA0 input voltage is lower than the ADLT threshold or higher than the ADGT threshold.

Two 100 kΩ resistors are used to emulate the thermistor potential divider, and the current consumption is about 16 μA (3.3 V/200000) when the Enable Sensor signal is high.

The PRS channel signal can route to a GPIO pin for debugging or to use it as an enable signal. Table 5.3 GPIO Pins Used for PRS Channels on page 23 shows which GPIO pins are used in this example for different PRS channels.

Except GPIO for PRS channel 4 (Sensor Enable), all PRS channel outputs are disabled by default to reduce the current consumption. Set the PRS_DEBUG_OUT define in prs_rtcc_logic.c to 1 to enable all PRS channel outputs.

| 5           | RTCC_Event      | PD11  | 1                    | Pin 10 of J102
|             |                 |       |                      | Pin 11 of EXP Header       |

The timing diagram of the PRS channels is shown in the figure below. The RTCC trigger pulse width is about 1 ms (ULFRCO), and the ADC sampling frequency is about 100 Hz.
The Figure 5.5 Timing Diagram of PRS Channel 0, 4, and 5 on page 24 matches with the diagram in Figure 5.1 ADC Sample Triggered by RTCC Event through PRS on page 19. The Enable Sensor pulse width includes the delay to start the 13 MHz AUXHFRCO oscillator, and the ADC warmup and sample time is 6.875 μs.

Press the push button BTN1 to select [RTCC Triggered ADC Conversion with Configurable PRS Logic in EM3].

Example 5
RTCC Triggered
ADC Conversion
with Configurable
PRS Logic in EM3

Press BTN1 to next menu
Press BTN0 to start

Press push button BTN0 to place the EFM32 Pearl Gecko into Energy Mode 3 (EM3).

Example 5
RTCC Triggered
ADC Conversion
with Configurable
PRS Logic in EM3

Sleep in EM3

Wakeup if voltage in PA0 is outside the compare window (0.5V – 3V)

Press BTN1 to exit

The MCU wakes up when the ADC SINGCMP interrupt triggers, and voltages in the latest single FIFO display on the Memory LCD as shown below.
Example 5
RTCC Triggered
ADC Conversion
with Configurable
PRS Logic in EM3
ADC Compare Interrupt
FIFO 0: 1.4212V
FIFO 1: 1.4212V
FIFO 2: 1.4212V
FIFO 3: 0.0008V
Press BTN1 to exit

To measure the current consumption in Energy Mode 3 (EM3), the debugger must be disconnected from the IDE. Then, switch the power selector on the EFM32 Pearl Gecko Starter Kit to the "BAT" position and then back to the "AEM" position to provide a Power-on Reset (POR) to the DC-DC converter.

The average current consumption of this example is about 2.77 µA (measured by Energy Profiler in Simplicity Studio), and this figure includes the power consumption of the inactive Memory LCD on the EFM32PG STK.

Figure 5.6. Current Consumption of Configurable PRS Logic Example
6. Revision History

6.1 Revision 1.08
2016-11-18
Updated example code for EFM32 Gecko Series 0
Added example code for EFM32 Gecko Series 1
Updated document for EFM32 Gecko Series 1

6.2 Revision 1.07
2014-05-07
Updated example code to CMSIS 3.20.5
Changed to Silicon Labs license on code examples
Added project files for Simplicity IDE
Removed makefiles for Sourcery CodeBench Lite

6.3 Revision 1.06
2013-10-14
New cover layout

6.4 Revision 1.05
2013-05-08
Added software projects for ARM-GCC and Atollic TrueStudio.

6.5 Revision 1.04
2012-11-12
Adapted software projects to new kit-driver and bsp structure.
Added software support for Tiny and Giant Gecko STK.

6.6 Revision 1.03
2012-04-20
Adapted software projects to new peripheral library naming and CMSIS_V3.

6.7 Revision 1.02
2011-10-21
Updated IDE project paths with new kits directory.

6.8 Revision 1.01
2011-05-18
Updated projects to align with new bsp version.

6.9 Revision 1.00
2010-12-13
Initial revision.
