3.2 HCSL Differential Output Terminations

Termination for HCSL Outputs

The Si52254/8 HCSL driver features integrated termination resistors to simplify interfacing to an HCSL receiver. The HCSL driver supports both 100 Ω and 85 Ω transmission line options, and can be selected using the IMP_SEL hardware input pin.

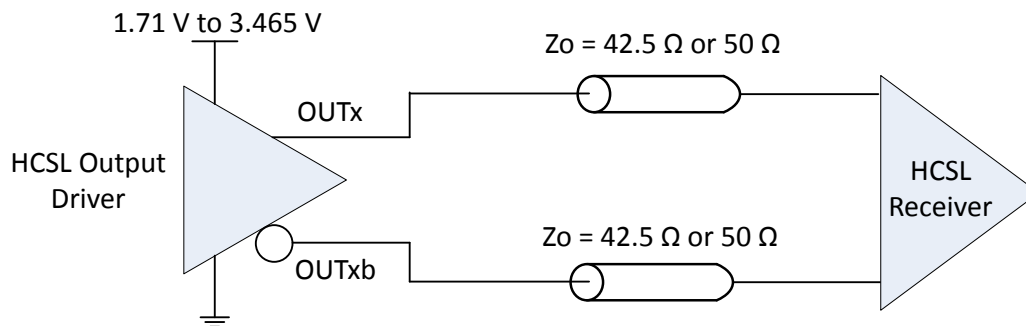

Figure 3.5. HCSL Internal Termination Mode

3.3 Output Enable/Disable

An output enable pin provides a convenient method of disabling or enabling the output drivers. When the output enable pin is held high, all designated outputs will be disabled. When held low, the designated outputs will be enabled.

3.4 Loss of Signal (LOS)

The LOS indicator is used to check for the presence of an input reference source (crystal or clock). LOS will assert when the reference source frequency drops below 10 MHz.

The LOS pin must be checked prior to selecting the clock input or should be polled to check for the presence of the currently selected input clock. In the event that a reference source is not present, the associated LOS pin will assume a logic low (LOS = 0) state. When a reference source is present at the associated input clock pin, the LOS pin will assume a logic high (LOS = 1) state.

4. Power Supply Filtering Recommendations

The Si53258/4 features internal LDOs on each power supply pin, providing excellent power supply noise rejection. As a guideline, each power supply pin should use a parallel combination of a 1 μf and a 0.1 μF bypass capacitor placed as close to the supply pin as possible.

Notes:

1. For best jitter performance, keep the midpoint differential input slew rate faster than 0.3 V/ns.
2. For best jitter performance, keep the midpoint input single ended slew rate faster than 1 V/ns.
3. Input capacitance on crystal pins targets 23 pf each plus 1 pf external trace capacitance to provide 12 pf series equivalent crystal load capacitance.
4. Measured at crossing point where the instantaneous voltage value of the rising edge of CLK equals the falling edge of CLK#.
5. Measure taken from differential waveform on a component test board. The edge (slew) rate is measured from -150mV to +150mV on the differential waveform. Scope is set to average because the scope sample clock is making most of the dynamic wiggles along the clock edge Only valid for Rising clock and Falling Clock#. Signal must be monotonic through the Vol to Voh region for Trise and Tfall.
6. This measurement refers to the total variation from the lowest crossing point to the highest, regardless of which edge is crossing.
7. Vcross(rel) Min and Max are derived using the following, Vcross(rel) Min = 0.250 + 0.5 (Vhavg - 0.700), Vcross(rel) Max = 0.550 - 0.5 (0.700 - Vhavg).
8. Measurement taken from Single Ended waveform.
9. Measurement taken from differential waveform VLow Math function.
10. Overshoot is defined as the absolute value of the maximum voltage.
11. Undershoot is defined as the absolute value of the minimum voltage.
12. The crossing point must meet the absolute and relative crossing point specifications simultaneously.
13. ΔVcross is defined as the total variation of all crossing voltages of Rising CLOCK and Falling CLOCK#. This is the maximum allowed variance in Vcross for any particular system.
14. Measured with oscilloscope, averaging off, using min max statistics. Variation is the delta between min and max.
