

EFR32xG12 Wireless Gecko Reference Manual

The Wireless Gecko portfolio of SoCs (EFR32) include the EFR32MG12, EFR32BG12, and EFR32FG12 families. With support for Zigbee[®], Thread, Bluetooth Low Energy (BLE) and proprietary protocols, the Wireless Gecko portfolio is ideal for enabling energy-friendly wireless networking for IoT devices.

The single-die solution provides industry-leading energy efficiency, ultra-fast wakeup times, a scalable high-power amplifier, an integrated balun and no-compromise MCU features.

KEY FEATURES

- 32-bit ARM® Cortex-M4 core with 40 MHz maximum operating frequency
- Scalable Memory and Radio configuration options available in several footprint compatible QFN packages
- 12-channel Peripheral Reflex System enabling autonomous interaction of MCU peripherals
- Autonomous Hardware Crypto Accelerator and Random Number Generator
- Integrated balun for 2.4 GHz and integrated PA with up to 19.5 dBm transmit power for 2.4 GHz and 20 dBm transmit power for Sub-GHz radios
- · Integrated dc-dc with RF noise mitigation

I1. CMU - Clock Management Unit	.300
11.1 Introduction	. 300
11.2 Features	. 300
11.3 Functional Description	. 301
11.3.1 System Clocks	
11.3.2 Oscillators	
11.3.3 Configuration for Operating Frequencies	. 323
11.3.4 Energy Modes	
11.3.5 Clock Output on a Pin	
11.3.6 Clock Input From a Pin	
11.3.7 Clock Output on PRS	
11.3.8 Error Handling	
11.3.10 Wake-up	
11.3.11 Protection	
11.4 Register Map	
11.5 Register Description	
11.5.1 CMU_CTRL - CMU Control Register	
11.5.2 CMU_HFRCOCTRL - HFRCO Control Register	
11.5.3 CMU_AUXHFRCOCTRL - AUXHFRCO Control Register	
11.5.4 CMU_LFRCOCTRL - LFRCO Control Register	
11.5.5 CMU_HFXOCTRL - HFXO Control Register	
11.5.6 CMU_HFXOSTARTUPCTRL - HFXO Startup Control	
11.5.7 CMU_HFXOSTEADYSTATECTRL - HFXO Steady State Control	. 339
11.5.8 CMU_HFXOTIMEOUTCTRL - HFXO Timeout Control	
11.5.9 CMU_LFXOCTRL - LFXO Control Register	
11.5.10 CMU_CALCTRL - Calibration Control Register	
11.5.11 CMU_CALCNT - Calibration Counter Register	
11.5.12 CMU_OSCENCMD - Oscillator Enable/Disable Command Register	
11.5.13 CMU_CMD - Command Register	
11.5.14 CMU_DBGCLKSEL - Debug Trace Clock Select	
11.5.15 CMU_HFCLKSEL - High Frequency Clock Select Command Register	
11.5.16 CMU_LFACLKSEL - Low Frequency A Clock Select Register	
11.5.17 CMU_LFBCLKSEL - Low Frequency B Clock Select Register	
11.5.18 CMU_LFECLKSEL - Low Frequency E Clock Select Register	
11.5.19 CMU_STATUS - Status Register	
11.5.20 CMU_HFCLKSTATUS - HFCLK Status Register	
11.5.22 CMU_IF - Interrupt Flag Register	
11.5.23 CMU_IFS - Interrupt Flag Set Register	
11.5.24 CMU_IFC - Interrupt Flag Clear Register	
11.5.25 CMU IEN - Interrupt Enable Register	
11.5.26 CMU_HFBUSCLKEN0 - High Frequency Bus Clock Enable Register 0	
11.5.27 CMU HFPERCLKEN0 - High Frequency Peripheral Clock Enable Register 0	

11.5.28 CMU_HFRADIOALTCLKEN0 - High Frequency Alternate Radio Peripheral Clock	
Register 0	
11.5.29 CMU_LFACLKEN0 - Low Frequency a Clock Enable Register 0 (Async Reg)	
	367
	368
11.5.32 CMU_HFPRESC - High Frequency Clock Prescaler Register	
11.5.33 CMU_HFCOREPRESC - High Frequency Core Clock Prescaler Register	370
11.5.34 CMU_HFPERPRESC - High Frequency Peripheral Clock Prescaler Register .	370
11.5.35 CMU_HFRADIOPRESC - High Frequency Radio Peripheral Clock Prescaler Reg	
	371
11.5.37 CMU_LFAPRESC0 - Low Frequency a Prescaler Register 0 (Async Reg) 11.5.38 CMU LFBPRESC0 - Low Frequency B Prescaler Register 0 (Async Reg)	372
	373
11.5.40 CMU_HFRADIOALTPRESC - High Frequency Alternate Radio Peripheral Clock F	
Register	
11.5.41 CMU_SYNCBUSY - Synchronization Busy Register	
11.5.42 CMU_FREEZE - Freeze Register	
11.5.43 CMU PCNTCTRL - PCNT Control Register	
11.5.44 CMU ADCCTRL - ADC Control Register	
11.5.45 CMU_ROUTEPEN - I/O Routing Pin Enable Register	
11.5.46 CMU_ROUTELOC0 - I/O Routing Location Register	
11.5.47 CMU_ROUTELOC1 - I/O Routing Location Register	383
11.5.48 CMU_LOCK - Configuration Lock Register	384
12. SMU - Security Management Unit	385
12.1 Introduction	385
12.2 Features	
12.3 Functional Description	
12.3.1 PPU - Peripheral Protection Unit	
12.4 Register Map	
12.5 Register Description	
12.5.1 SMU_IF - Interrupt Flag Register	
12.5.2 SMU_IFS - Interrupt Flag Set Register	
12.5.3 SMU_IFC - Interrupt Flag Clear Register	
12.5.4 SMU_IEN - Interrupt Enable Register	
12.5.5 SMU_PPUCTRL - PPU Control Register	
12.5.7 SMU_PPUPATD1 - PPU Privilege Access Type Descriptor 1	
12.5.8 SMU_PPUFS - PPU Fault Status	
_	
13. RTCC - Real Time Counter and Calendar	398
13.1 Introduction	398
13.2 Features	398
13.3 Functional Description	399
13.3.1 Counter	400
13.3.2 Capture/Compare Channels	404

13.3.3 Interrupts and PRS Output	. 406
13.3.4 Energy Mode Availability	. 407
13.3.5 Register Lock	. 407
13.3.6 Oscillator Failure Detection	. 407
13.3.7 Retention Registers	. 407
13.3.8 Debug Session	. 407
13.4 Register Map	. 408
13.5 Register Description	. 409
13.5.1 RTCC_CTRL - Control Register (Async Reg)	. 409
13.5.2 RTCC_PRECNT - Pre-Counter Value Register (Async Reg)	.411
13.5.3 RTCC_CNT - Counter Value Register (Async Reg)	. 411
13.5.4 RTCC_COMBCNT - Combined Pre-Counter and Counter Value Register	. 412
13.5.5 RTCC_TIME - Time of Day Register (Async Reg)	
13.5.6 RTCC_DATE - Date Register (Async Reg)	
13.5.7 RTCC_IF - RTCC Interrupt Flags	
13.5.8 RTCC_IFS - Interrupt Flag Set Register	
13.5.9 RTCC_IFC - Interrupt Flag Clear Register	
13.5.10 RTCC_IEN - Interrupt Enable Register	
13.5.11 RTCC_STATUS - Status Register	
13.5.12 RTCC_CMD - Command Register (Async Reg)	
13.5.13 RTCC_SYNCBUSY - Synchronization Busy Register	
13.5.14 RTCC_POWERDOWN - Retention RAM Power-down Register (Async Reg)	
13.5.15 RTCC_LOCK - Configuration Lock Register (Async Reg)	
13.5.16 RTCC_EM4WUEN - Wake Up Enable	
13.5.17 RTCC_CCx_CTRL - CC Channel Control Register (Async Reg)	
13.5.18 RTCC_CCx_CCV - Capture/Compare Value Register (Async Reg)	
13.5.19 RTCC_CCx_TIME - Capture/Compare Time Register (Async Reg)	
13.5.20 RTCC_CCx_DATE - Capture/Compare Date Register (Async Reg)	
13.5.21 RTCC_RETx_REG - Retention Register	. 426
14. WDOG - Watchdog Timer	427
14.1 Introduction	. 427
14.2 Features	. 427
14.3 Functional Description	. 427
14.3.1 Clock Source	
14.3.2 Debug Functionality	428
14.3.3 Energy Mode Handling	428
14.3.4 Register Access	. 428
14.3.5 Warning Interrupt	.428
14.3.6 Window Interrupt	429
14.3.7 PRS as Watchdog Clear	
14.3.8 PRS Rising Edge Monitoring	430
14.4 Register Map	
14.5 Register Description	. 432
14.5.1 WDOG_CTRL - Control Register (Async Reg)	. 432
14.5.2 WDOG_CMD - Command Register (Async Reg)	.435
14.5.3 WDOG SYNCBUSY - Synchronization Busy Register	436

14.5.4 WDOGn_PCHx_PRSCTRL - PRS Control Register (Async Reg)	437
14.5.5 WDOG_IF - Watchdog Interrupt Flags	438
14.5.6 WDOG_IFS - Interrupt Flag Set Register	439
14.5.7 WDOG_IFC - Interrupt Flag Clear Register	.440
14.5.8 WDOG_IEN - Interrupt Enable Register	.441
15. PRS - Peripheral Reflex System	442
15.1 Introduction	442
15.2 Features	442
15.3 Functional Description	. 443
15.3.1 Channel Functions	443
15.3.2 Producers	444
15.3.3 Consumers	
15.3.4 Event on PRS	
15.3.5 DMA Request on PRS	
15.3.6 Example	.447
15.4 Register Map	. 447
15.5 Register Description	448
15.5.1 PRS_SWPULSE - Software Pulse Register	448
15.5.2 PRS_SWLEVEL - Software Level Register	.449
15.5.3 PRS_ROUTEPEN - I/O Routing Pin Enable Register	
15.5.4 PRS_ROUTELOC0 - I/O Routing Location Register	
15.5.5 PRS_ROUTELOC1 - I/O Routing Location Register	
15.5.6 PRS_ROUTELOC2 - I/O Routing Location Register	
15.5.7 PRS_CTRL - Control Register	
15.5.8 PRS_DMAREQ0 - DMA Request 0 Register	
15.5.9 PRS_DMAREQ1 - DMA Request 1 Register	
15.5.10 PRS_PEEK - PRS Channel Values	
15.5.11 PRS_CHx_CTRL - Channel Control Register	462
16. PCNT - Pulse Counter	469
16.1 Introduction	469
16.2 Features	469
16.3 Functional Description	. 470
16.3.1 Pulse Counter Modes	
16.3.2 Hysteresis	477
16.3.3 Auxiliary Counter	.478
16.3.4 Triggered Compare and Clear	
16.3.5 Register Access	480
16.3.6 Clock Sources	.480
16.3.7 Input Filter	
16.3.8 Edge Polarity	
16.3.9 PRS and PCNTn_S0IN,PCNTn_S1IN Inputs	
16.3.10 Interrupts	
16.3.11 Cascading Pulse Counters	483
16.4 Register Map	. 484

16.5 Register Description	. 485
16.5.1 PCNTn_CTRL - Control Register (Async Reg)	485
16.5.2 PCNTn_CMD - Command Register (Async Reg)	489
16.5.3 PCNTn_STATUS - Status Register	489
16.5.4 PCNTn_CNT - Counter Value Register	. 490
16.5.5 PCNTn_TOP - Top Value Register	490
16.5.6 PCNTn_TOPB - Top Value Buffer Register (Async Reg)	. 491
16.5.7 PCNTn_IF - Interrupt Flag Register	. 491
16.5.8 PCNTn_IFS - Interrupt Flag Set Register	492
16.5.9 PCNTn_IFC - Interrupt Flag Clear Register	493
16.5.10 PCNTn_IEN - Interrupt Enable Register	494
16.5.11 PCNTn_ROUTELOC0 - I/O Routing Location Register	
16.5.12 PCNTn_FREEZE - Freeze Register	497
16.5.13 PCNTn_SYNCBUSY - Synchronization Busy Register	
16.5.14 PCNTn_AUXCNT - Auxiliary Counter Value Register	
16.5.15 PCNTn_INPUT - PCNT Input Register	
16.5.16 PCNTn_OVSCFG - Oversampling Config Register (Async Reg)	. 500
17. I2C - Inter-Integrated Circuit Interface	. 501
17.1 Introduction	
17.2 Features	
17.3 Functional Description	
17.3.1 I2C-Bus Overview	
17.3.2 Enable and Reset	
17.3.3 Safely Disabling and Changing Slave Configuration.	
17.3.4 Clock Generation	
17.3.5 Arbitration	
17.3.6 Buffers	
17.3.7 Master Operation	
17.3.8 Bus States	
17.3.9 Slave Operation	
17.3.10 Transfer Automation	
17.3.11 Using 10-bit Addresses	
17.3.12 Error Handling	
17.3.13 DMA Support	
17.3.14 Interrupts	
17.3.15 Wake-up	
17.4 Register Map	
17.5 Register Description	
17.5.1 I2Cn_CTRL - Control Register	
17.5.2 I2Cn_CMD - Command Register	
17.5.2 I2Cn_STATE - State Register	
17.5.4 I2Cn_STATUS - Status Register	
17.5.5 I2Cn_CLKDIV - Clock Division Register	
17.5.6 I2Cn_SADDR - Slave Address Register	
17.5.7 I2Cn_SADDRMASK - Slave Address Mask Register	
17.5.8 I2Cn RXDATA - Receive Buffer Data Register (Actionable Reads)	
17.5.8 J2Cn RXDATA - Receive Buffer Data Register (Actionable Reads)	534

17.5.9 I2Cn_RXDOUBLE - Receive Buffer Double Data Register (Actionable Reads)	535
17.5.10 I2Cn_RXDATAP - Receive Buffer Data Peek Register	. 535
17.5.11 I2Cn_RXDOUBLEP - Receive Buffer Double Data Peek Register	. 536
17.5.12 I2Cn_TXDATA - Transmit Buffer Data Register	536
17.5.13 I2Cn_TXDOUBLE - Transmit Buffer Double Data Register	. 537
17.5.14 I2Cn_IF - Interrupt Flag Register	538
17.5.15 I2Cn_IFS - Interrupt Flag Set Register	540
17.5.16 I2Cn_IFC - Interrupt Flag Clear Register	. 542
17.5.17 I2Cn_IEN - Interrupt Enable Register	. 544
17.5.18 I2Cn_ROUTEPEN - I/O Routing Pin Enable Register	545
17.5.19 I2Cn_ROUTELOC0 - I/O Routing Location Register	. 546
18. USART - Universal Synchronous Asynchronous Receiver/Transmitter	549
18.1 Introduction	. 549
18.2 Features	. 550
18.3 Functional Description	. 551
18.3.1 Modes of Operation	. 552
18.3.2 Asynchronous Operation	. 552
18.3.3 Synchronous Operation	. 569
18.3.4 Hardware Flow Control	575
18.3.5 Debug Halt	. 575
18.3.6 PRS-triggered Transmissions	. 575
18.3.7 PRS RX Input	575
18.3.8 PRS CLK Input	. 576
18.3.9 DMA Support	. 576
18.3.10 Timer	. 577
18.3.11 Interrupts	. 582
18.3.12 IrDA Modulator/ Demodulator	. 583
18.4 Register Map	. 584
18.5 Register Description	. 585
18.5.1 USARTn_CTRL - Control Register	
18.5.2 USARTn_FRAME - USART Frame Format Register	
18.5.3 USARTn_TRIGCTRL - USART Trigger Control Register	
18.5.4 USARTn_CMD - Command Register	
18.5.5 USARTn_STATUS - USART Status Register	
18.5.6 USARTn CLKDIV - Clock Control Register	
18.5.7 USARTn_RXDATAX - RX Buffer Data Extended Register (Actionable Reads)	597
18.5.8 USARTn RXDATA - RX Buffer Data Register (Actionable Reads)	
18.5.9 USARTn_RXDOUBLEX - RX Buffer Double Data Extended Register (Actionable Reads)	598
18.5.10 USARTn_RXDOUBLE - RX FIFO Double Data Register (Actionable Reads)	. 599
18.5.11 USARTn_RXDATAXP - RX Buffer Data Extended Peek Register	
18.5.12 USARTn_RXDOUBLEXP - RX Buffer Double Data Extended Peek Register	
18.5.13 USARTn_TXDATAX - TX Buffer Data Extended Register	
18.5.14 USARTn_TXDATA - TX Buffer Data Register	
18.5.15 USARTn_TXDOUBLEX - TX Buffer Double Data Extended Register	
18.5.16 USARTn_TXDOUBLE - TX Buffer Double Data Register	
18.5.17 USARTn_IF - Interrupt Flag Register	

18.5.18 USARTn_IFS - Interrupt Flag Set Register	607
18.5.19 USARTn_IFC - Interrupt Flag Clear Register	
18.5.20 USARTn_IEN - Interrupt Enable Register	
18.5.21 USARTn_IRCTRL - IrDA Control Register	
18.5.22 USARTn_INPUT - USART Input Register	615
18.5.23 USARTn_I2SCTRL - I2S Control Register	617
18.5.24 USARTn_TIMING - Timing Register	
18.5.25 USARTn_CTRLX - Control Register Extended	621
18.5.26 USARTn_TIMECMP0 - Used to Generate Interrupts and Various Delay	s 622
18.5.27 USARTn_TIMECMP1 - Used to Generate Interrupts and Various Delay	s 624
18.5.28 USARTn_TIMECMP2 - Used to Generate Interrupts and Various Delay	s 626
18.5.29 USARTn_ROUTEPEN - I/O Routing Pin Enable Register	628
18.5.30 USARTn_ROUTELOC0 - I/O Routing Location Register	
18.5.31 USARTn_ROUTELOC1 - I/O Routing Location Register	
19. LEUART - Low Energy Universal Asynchronous Receiver/Transmitter	638
19.1 Introduction	
19.2 Features	
19.3 Functional Description	
19.3.2 Clock Source	
19.3.3 Clock Generation	
19.3.4 Data Transmission	
19.3.5 Data Reception	
19.3.6 Loopback	
19.3.7 Half Duplex Communication	
19.3.8 Transmission Delay	
19.3.9 PRS RX Input	
19.3.10 DMA Support	
19.3.11 Pulse Generator/ Pulse Extender	
19.3.12 Register Access	
19.4 Register Map	
19.5 Register Description	
19.5.1 LEUARTn_CTRL - Control Register (Async Reg)	
19.5.2 LEUARTn_CMD - Command Register (Async Reg)	
19.5.3 LEUARTn_STATUS - Status Register	
19.5.4 LEUARTn_CLKDIV - Clock Control Register (Async Reg)	
19.5.5 LEUARTn_STARTFRAME - Start Frame Register (Async Reg)	
19.5.6 LEUARTn_SIGFRAME - Signal Frame Register (Async Reg)	
19.5.7 LEUARTn_RXDATAX - Receive Buffer Data Extended Register (Actiona	•
19.5.8 LEUARTn_RXDATA - Receive Buffer Data Register (Actionable Reads)	
19.5.9 LEUARTn_RXDATAXP - Receive Buffer Data Extended Peek Register	
19.5.10 LEUARTn_TXDATAX - Transmit Buffer Data Extended Register (Async	
19.5.11 LEUARTn_TXDATA - Transmit Buffer Data Register (Async Reg)	
19.5.12 LEUARTn_IF - Interrupt Flag Register	
19.5.13 LEUARTn_IFS - Interrupt Flag Set Register	
19.5.14 LEUARTn IFC - Interrupt Flag Clear Register	663

19.5.15 LEUARTn_IEN - Interrupt Enable Register	. 664
19.5.16 LEUARTn_PULSECTRL - Pulse Control Register (Async Reg)	. 665
19.5.17 LEUARTn_FREEZE - Freeze Register	.666
19.5.18 LEUARTn_SYNCBUSY - Synchronization Busy Register	. 667
19.5.19 LEUARTn_ROUTEPEN - I/O Routing Pin Enable Register	. 668
19.5.20 LEUARTn_ROUTELOC0 - I/O Routing Location Register	. 669
19.5.21 LEUARTn_INPUT - LEUART Input Register	.672
20. TIMER/WTIMER - Timer/Counter	. 673
20.1 Introduction	. 673
20.2 Features	
20.3 Functional Description	675
20.3.1 Counter Modes	
20.3.2 Compare/Capture Channels	
20.3.3 Dead-Time Insertion Unit	
20.3.4 Debug Mode	
20.3.5 Interrupts, DMA and PRS Output	
20.3.6 GPIO Input/Output	
20.4 Register Map	
20.5 Register Description	
20.5.1 TIMERn_CTRL - Control Register	
20.5.2 TIMERn_CMD - Command Register	
20.5.3 TIMERn_STATUS - Status Register	
20.5.4 TIMERn IF - Interrupt Flag Register	
20.5.5 TIMERn_IFS - Interrupt Flag Set Register	
20.5.6 TIMERn_IFC - Interrupt Flag Clear Register	
20.5.7 TIMERn IEN - Interrupt Enable Register	
20.5.8 TIMERn TOP - Counter Top Value Register	
20.5.9 TIMERn_TOPB - Counter Top Value Buffer Register	. 709
20.5.10 TIMERn_CNT - Counter Value Register	
20.5.11 TIMERn_LOCK - TIMER Configuration Lock Register	. 710
20.5.12 TIMERn_ROUTEPEN - I/O Routing Pin Enable Register	
20.5.13 TIMERn_ROUTELOC0 - I/O Routing Location Register	. 712
20.5.14 TIMERn_ROUTELOC2 - I/O Routing Location Register	. 717
20.5.15 TIMERn_CCx_CTRL - CC Channel Control Register	. 721
20.5.16 TIMERn_CCx_CCV - CC Channel Value Register (Actionable Reads)	. 724
20.5.17 TIMERn_CCx_CCVP - CC Channel Value Peek Register	. 724
20.5.18 TIMERn_CCx_CCVB - CC Channel Buffer Register	. 725
20.5.19 TIMERn_DTCTRL - DTI Control Register	.726
20.5.20 TIMERn_DTTIME - DTI Time Control Register	. 728
20.5.21 TIMERn_DTFC - DTI Fault Configuration Register	.730
20.5.22 TIMERn_DTOGEN - DTI Output Generation Enable Register	. 732
20.5.23 TIMERn_DTFAULT - DTI Fault Register	. 7.33
20.5.24 TIMERn_DTFAULTC - DTI Fault Clear Register	. 734
20.5.25 TIMERn_DTLOCK - DTI Configuration Lock Register	.735
21. LETIMER - Low Energy Timer	. 736
21.1 Introduction	736

21.2 Features	. 7.36
21.3 Functional Description	737
21.3.2 Compare Registers	
21.3.3 Top Value	
21.3.4 Underflow Output Action	
21.3.5 PRS Output	
21.3.6 Examples	
21.3.7 Register Access	. 749
21.4 Register Map	. 750
21.5 Register Description	. 751
21.5.1 LETIMERn_CTRL - Control Register (Async Reg)	. 751
21.5.2 LETIMERn_CMD - Command Register (Async Reg)	. 753
21.5.3 LETIMERn_STATUS - Status Register	. 753
21.5.4 LETIMERn_CNT - Counter Value Register	754
21.5.5 LETIMERn_COMP0 - Compare Value Register 0 (Async Reg)	. 754
21.5.6 LETIMERn_COMP1 - Compare Value Register 1 (Async Reg)	. 755
21.5.7 LETIMERn_REP0 - Repeat Counter Register 0 (Async Reg)	.755
21.5.8 LETIMERn_REP1 - Repeat Counter Register 1 (Async Reg)	.756
21.5.9 LETIMERn_IF - Interrupt Flag Register	. 756
21.5.10 LETIMERn_IFS - Interrupt Flag Set Register	.757
21.5.11 LETIMERn_IFC - Interrupt Flag Clear Register	. 758
21.5.12 LETIMERn_IEN - Interrupt Enable Register	. 759
21.5.13 LETIMERn_SYNCBUSY - Synchronization Busy Register	. 7.59
21.5.14 LETIMERn_ROUTEPEN - I/O Routing Pin Enable Register	.760
21.5.15 LETIMERn_ROUTELOC0 - I/O Routing Location Register	. 761
21.5.16 LETIMERn_PRSSEL - PRS Input Select Register	. 764
22. CRYOTIMER - Ultra Low Energy Timer/Counter	. 767
22.1 Introduction	
22.2 Features	. 7.67
22.3 Functional Description	. 767
22.3.1 Block Diagram	
22.3.2 Operation	. 769
22.3.3 Debug Mode	
22.3.4 Energy Mode Availability	. 769
22.4 Register Map	. 770
22.5 Register Description	. 771
22.5.1 CRYOTIMER CTRL - Control Register	
22.5.2 CRYOTIMER_PERIODSEL - Interrupt Duration	
22.5.3 CRYOTIMER_CNT - Counter Value	
22.5.4 CRYOTIMER_EM4WUEN - Wake Up Enable	
22.5.5 CRYOTIMER IF - Interrupt Flag Register	
22.5.6 CRYOTIMER_IFS - Interrupt Flag Set Register	
22.5.7 CRYOTIMER IFC - Interrupt Flag Clear Register	
22.5.8 CRYOTIMER IFN - Interrunt Enable Register	

23	S. VDAC - Digital to Analog Converter	. 777
	23.1 Introduction	. 777
	23.2 Features	. 7.78
	23.3 Functional Description	
	23.3.1 Power Supply	
	23.3.2 I/O Pin Considerations	
	23.3.3 Enabling and Disabling a Channel	
	23.3.4 Conversions	
	23.3.5 Reference Selection	
	23.3.6 Warmup Time and Initial Conversion	
	23.3.7 Analog Output	
	23.3.8 Output Mode	
	23.3.9 Async Mode	
	23.3.10 Refresh Timer	
	23.3.11 Clock Prescaling	
	23.3.12 High Speed	
	23.3.13 Sine Generation Mode	
	23.3.14 Interrupt Flags	
	23.3.15 PRS Outputs	
	23.3.16 DMA Request	
	23.3.17 LESENSE Trigger Mode	
	23.3.18 Opamps	
	23.3.19 Calibration	
	23.3.20 Warmup Mode	
	23.4 Register Map	
	23.5 Register Description	
	23.5.1 VDACn_CTRL - Control Register	
	23.5.3 VDACn_CH0CTRL - Channel 0 Control Register	
	23.5.4 VDACn_CH1CTRL - Channel 1 Control Register	
	23.5.5 VDACn_CMD - Command Register	
	23.5.6 VDACn_IF - Interrupt Flag Register	
	23.5.7 VDACn_IFS - Interrupt Flag Set Register	
	23.5.8 VDACn_IFC - Interrupt Flag Clear Register	
	23.5.9 VDACn_IEN - Interrupt Enable Register	
	23.5.10 VDACn_CH0DATA - Channel 0 Data Register	
	—	
	23.5.12 VDACn_COMBDATA - Combined Data Register	
	23.5.13 VDACn_CAL - Calibration Register	
	23.5.14 VDACn_OPAx_APORTREQ - Operational Amplifier APORT Request Status Register .	
	23.5.15 VDACn_OPAx_APORTCONFLICT - Operational Amplifier APORT Conflict Status Registe	
	23.5.16 VDACn_OPAx_CTRL - Operational Amplifier Control Register	
	23.5.17 VDACn_OPAx_TIMER - Operational Amplifier Timer Control Register	
	23.5.18 VDACn_OPAx_MUX - Operational Amplifier Mux Configuration Register	
	23.5.19 VDACn_OPAx_OUT - Operational Amplifier Output Configuration Register	
	23.5.20 VDACn_OPAx_CAL - Operational Amplifier Calibration Register	819

24. OPAMP - Operational Amplifier	.821
24.1 Introduction	821
24.2 Features	821
24.3 Functional Description	. 822
24.3.1 Opamp Configuration	823
24.3.2 Interrupts and PRS Output	. 826
24.3.3 APORT Request and Conflict Status	
24.3.4 Opamp Modes	
24.3.5 Opamp VDAC Combination	. 833
24.4 Register Map	. 834
24.5 Register Description	. 834
25. ACMP - Analog Comparator	835
25.1 Introduction	835
25.2 Features	836
25.3 Functional Description	. 837
25.3.1 Power Supply	837
25.3.2 Warm-up Time	838
25.3.3 Response Time	
25.3.4 Hysteresis	
25.3.5 Input Pin Considerations	
25.3.6 Input Selection	
25.3.7 Capacitive Sense Mode	
25.3.8 Interrupts and PRS Output	
25.3.9 Output to GPIO	
25.3.10 APORT Connicts	
25.3.11 Supply Voltage Monitoring	
25.4 Register Map	
25.5 Register Description	. 845
25.5.1 ACMPn_CTRL - Control Register	
25.5.2 ACMPn_INPUTSEL - Input Selection Register	
25.5.3 ACMPn_STATUS - Status Register	
25.5.4 ACMPn_IF - Interrupt Flag Register	854
25.5.5 ACMPn_IFS - Interrupt Flag Set Register	. 854
25.5.6 ACMPn_IFC - Interrupt Flag Clear Register	
25.5.7 ACMPn_IEN - Interrupt Enable Register	
25.5.8 ACMPn_APORTREQ - APORT Request Status Register	
25.5.9 ACMPn_APORTCONFLICT - APORT Conflict Status Register	
25.5.10 ACMPn_HYSTERESIS0 - Hysteresis 0 Register	
25.5.11 ACMPn_HYSTERESIS1 - Hysteresis 1 Register	
25.5.12 ACMPn_ROUTEPEN - I/O Routing Pine Enable Register	
25.5.13 ACMPn_ROUTELOC0 - I/O Routing Location Register	
25.5.14 ACMPn_EXTIFCTRL - External Override Interface Control	
26. ADC - Analog to Digital Converter	.867

26.1 Introduction	. 867
26.2 Features	. 868
26.3 Functional Description	. 869
26.3.1 Clock Selection	
26.3.2 Conversions	. 870
26.3.3 ADC Modes	. 871
26.3.4 Warm-up Time	.872
26.3.5 Power Supply	873
26.3.6 Input Pin Considerations	. 873
26.3.7 Input Selection	. 874
26.3.8 Reference Selection and Input Range Definition	. 878
26.3.9 Programming of Bias Current	.882
26.3.10 Feature Set	
26.3.11 Interrupts, PRS Output	. 889
26.3.12 DMA Request	. 889
26.3.13 Calibration	. 889
26.3.14 EM2 Deep Sleep or EM3 Stop Operation	. 890
26.3.15 ASYNC ADC_CLK Usage Restrictions and Benefits	. 891
26.3.16 Window Compare Function	891
26.3.17 ADC Programming Model	. 892
26.4 Register Map	. 893
26.5 Register Description	. 894
26.5.1 ADCn_CTRL - Control Register	
26.5.2 ADCn_CMD - Command Register	
26.5.3 ADCn_STATUS - Status Register	
26.5.4 ADCn_SINGLECTRL - Single Channel Control Register	
26.5.5 ADCn_SINGLECTRLX - Single Channel Control Register Continued	
26.5.6 ADCn SCANCTRL - Scan Control Register	
26.5.7 ADCn SCANCTRLX - Scan Control Register Continued	
26.5.8 ADCn_SCANMASK - Scan Sequence Input Mask Register	
26.5.9 ADCn SCANINPUTSEL - Input Selection Register for Scan Mode	
26.5.10 ADCn SCANNEGSEL - Negative Input Select Register for Scan	
26.5.11 ADCn CMPTHR - Compare Threshold Register	
26.5.12 ADCn_BIASPROG - Bias Programming Register for Various Analog Blocks Used in ADC	
Operation	. 922
26.5.13 ADCn_CAL - Calibration Register	. 923
26.5.14 ADCn_IF - Interrupt Flag Register	. 925
26.5.15 ADCn_IFS - Interrupt Flag Set Register	. 927
26.5.16 ADCn_IFC - Interrupt Flag Clear Register	.929
26.5.17 ADCn_IEN - Interrupt Enable Register	.931
26.5.18 ADCn_SINGLEDATA - Single Conversion Result Data (Actionable Reads)	. 932
26.5.19 ADCn_SCANDATA - Scan Conversion Result Data (Actionable Reads)	
26.5.20 ADCn_SINGLEDATAP - Single Conversion Result Data Peek Register	
26.5.21 ADCn_SCANDATAP - Scan Sequence Result Data Peek Register	
26.5.22 ADCn_SCANDATAX - Scan Sequence Result Data + Data Source Register (Actionable	
Reads)	. 934
26.5.23 ADCn SCANDATAXP - Scan Sequence Result Data + Data Source Peek Register	934

26.5.24 ADCn_APORTREQ - APORT Request Status Register	. 935
26.5.25 ADCn_APORTCONFLICT - APORT Conflict Status Register	. 936
26.5.26 ADCn_SINGLEFIFOCOUNT - Single FIFO Count Register	937
26.5.27 ADCn_SCANFIFOCOUNT - Scan FIFO Count Register	. 937
26.5.28 ADCn_SINGLEFIFOCLEAR - Single FIFO Clear Register	. 938
26.5.29 ADCn_SCANFIFOCLEAR - Scan FIFO Clear Register	
26.5.30 ADCn_APORTMASTERDIS - APORT Bus Master Disable Register	
27. IDAC - Current Digital to Analog Converter	
27.1 Introduction	. 942
27.2 Features	. 942
27.3 Functional Description	. 943
27.3.1 Current Programming	
27.3.2 IDAC Enable and Warm-up	
27.3.3 Output Control	
27.3.4 APORT Configuration	
27.3.5 Interrupts	
27.3.6 Minimizing Output Transition	
27.3.7 Duty Cycle Configuration.	
27.3.8 Calibration	
27.3.9 PRS Triggered Charge Injection	
27.4 Register Map	
27.5 Register Description	946
27.5.1 IDAC_CTRL - Control Register	
27.5.2 IDAC_CURPROG - Current Programming Register	
27.5.3 IDAC_DUTYCONFIG - Duty Cycle Configuration Register	
27.5.4 IDAC STATUS - Status Register	
27.5.5 IDAC_IF - Interrupt Flag Register	
27.5.6 IDAC IFS - Interrupt Flag Set Register	
27.5.7 IDAC_IFC - Interrupt Flag Clear Register	
27.5.8 IDAC_IEN - Interrupt Enable Register	
27.5.9 IDAC_APORTREQ - APORT Request Status Register	
27.5.10 IDAC_APORTCONFLICT - APORT Request Status Register	
28. LESENSE - Low Energy Sensor Interface	. 953
28.1 Introduction	. 953
28.2 Features	. 954
28.3 Functional Description	. 954
28.3.1 Channel Configuration	. 955
28.3.2 Scan Sequence	. 956
28.3.3 Sensor Timing	957
28.3.4 Sensor Interaction	
28.3.5 Sensor Sampling	960
28.3.6 Sensor Evaluation	. 961
28.3.7 Decoder	
28.3.8 Measurement Results	
28.3.9 VDAC Interface	. 967

28.3.10 ACMP Interface	967
28.3.11 ACMP and VDAC Duty Cycling	967
28.3.12 ADC Interface	967
28.3.13 DMA Requests	. 968
28.3.14 PRS Output	. 968
28.3.15 RAM	968
28.3.16 Application Examples	. 968
28.4 Register Map	974
28.5 Register Description	. 976
28.5.1 LESENSE_CTRL - Control Register (Async Reg)	
28.5.2 LESENSE_TIMCTRL - Timing Control Register (Async Reg)	
28.5.3 LESENSE_PERCTRL - Peripheral Control Register (Async Reg)	
28.5.4 LESENSE_DECCTRL - Decoder Control Register (Async Reg)	
28.5.5 LESENSE_BIASCTRL - Bias Control Register (Async Reg)	. 987
28.5.6 LESENSE_EVALCTRL - LESENSE Evaluation Control (Async Reg)	. 987
28.5.7 LESENSE_PRSCTRL - PRS Control Register (Async Reg)	. 988
28.5.8 LESENSE_CMD - Command Register (Async Reg)	989
28.5.9 LESENSE_CHEN - Channel Enable Register (Async Reg)	989
28.5.10 LESENSE_SCANRES - Scan Result Register (Async Reg)	990
28.5.11 LESENSE_STATUS - Status Register (Async Reg)	
28.5.12 LESENSE_PTR - Result Buffer Pointers (Async Reg)	992
28.5.13 LESENSE_BUFDATA - Result Buffer Data Register (Async Reg) (Actionable Reads)	
28.5.14 LESENSE_CURCH - Current Channel Index (Async Reg)	
28.5.15 LESENSE_DECSTATE - Current Decoder State (Async Reg)	
28.5.16 LESENSE_SENSORSTATE - Decoder Input Register (Async Reg)	
28.5.17 LESENSE_IDLECONF - GPIO Idle Phase Configuration (Async Reg)	
28.5.18 LESENSE_ALTEXCONF - Alternative Excite Pin Configuration (Async Reg)	
28.5.19 LESENSE_IF - Interrupt Flag Register	
28.5.20 LESENSE_IFS - Interrupt Flag Set Register	
28.5.21 LESENSE_IFC - Interrupt Flag Clear Register	
28.5.22 LESENSE_IEN - Interrupt Enable Register	
28.5.23 LESENSE_SYNCBUSY - Synchronization Busy Register	
28.5.24 LESENSE_ROUTEPEN - I/O Routing Register (Async Reg)	
28.5.25 LESENSE_STx_TCONFA - State Transition Configuration a (Async Reg)	
28.5.26 LESENSE_STx_TCONFB - State Transition Configuration B (Async Reg)	
28.5.27 LESENSE_BUFx_DATA - Scan Results (Async Reg)	
28.5.28 LESENSE_CHx_TIMING - Scan Configuration (Async Reg)	
28.5.30 LESENSE_CHx_EVAL - Scan Configuration (Async Reg)	
29. GPCRC - General Purpose Cyclic Redundancy Check	
29.1 Introduction	
29.2 Features	
29.3 Functional Description	
29.3.1 Polynomial Specification	
29.3.2 Input and Output Specification	
20.3.3 Initialization	1023

29.3.4 DMA Usage	
29.3.5 Byte-Level Bit Reversal and Byte Reordering	.1024
29.4 Register Map	. 1026
29.5 Register Description	. 1027
29.5.1 GPCRC_CTRL - Control Register	. 1.027
29.5.2 GPCRC_CMD - Command Register	. 1028
29.5.3 GPCRC_INIT - CRC Init Value	
29.5.4 GPCRC_POLY - CRC Polynomial Value	
29.5.5 GPCRC_INPUTDATA - Input 32-bit Data Register	
29.5.6 GPCRC_INPUTDATAHWORD - Input 16-bit Data Register	
29.5.7 GPCRC_INPUTDATABYTE - Input 8-bit Data Register	
29.5.8 GPCRC_DATA - CRC Data Register	
29.5.9 GPCRC_DATAREV - CRC Data Reverse Register	
30. TRNG - True Random Number Generator	. 1033
30.1 Introduction	. 1033
30.2 Features	. 1033
30.3 Functional Description	. 1034
30.3.1 Built-In Tests	.1034
30.3.2 FIFO Interface	
30.3.3 Data Format - Byte Ordering	
30.3.4 TRNG Usage	. 1035
30.4 Register Map	. 1037
30.5 Register Description

1. About This Document

1.1 Introduction

This document contains reference material for the EFR32xG12 Wireless Gecko devices. All modules and peripherals in the EFR32xG12 Wireless Gecko devices are described in general terms. Not all modules are present in all devices and the feature set for each device might vary. Such differences, including pinout, are covered in the device data sheets and applicable errata documents.

1.2 Conventions

Register Names

Register names are given with a module name prefix followed by the short register name:

TIMERn_CTRL - Control Register

The "n" denotes the module number for modules which can exist in more than one instance.

Some registers are grouped which leads to a group name following the module prefix:

GPIO Px DOUT - Port Data Out Register

The "x" denotes the different ports.

Bit Fields

Registers contain one or more bit fields which can be 1 to 32 bits wide. Bit fields wider than 1 bit are given with start (x) and stop (y) bit [y:x].

Bit fields containing more than one bit are unsigned integers unless otherwise is specified.

Unspecified bit field settings must not be used, as this may lead to unpredictable behaviour.

Address

The address for each register can be found by adding the base address of the module found in the Memory Map (see Figure 4.2 System Address Space With Core and Code Space Listing on page 46), and the offset address for the register (found in module Register Map).

Access Type

The register access types used in the register descriptions are explained in Table 1.1 Register Access Types on page 28.

Table 1.1. Register Access Types

Access Type	Description
R	Read only. Writes are ignored
RW	Readable and writable
RW1	Readable and writable. Only writes to 1 have effect
(R)W1	Sometimes readable. Only writes to 1 have effect. Currently only used for IFC registers (see 3.3.1.2 IFC Read-clear Operation)
W1	Read value undefined. Only writes to 1 have effect
W	Write only. Read value undefined.
RWH	Readable, writable, and updated by hardware
RW(nB), RWH(nB), etc.	"(nB)" suffix indicates that register explicitly does not support peripheral bit set or clear (see 4.2.3 Peripheral Bit Set and Clear)

Access Type	Description
	"(a)" suffix indicates that register has actionable reads (see 6.3.7 Debugger Reads of Actionable Registers)

Number format

0x prefix is used for hexadecimal numbers

0b prefix is used for binary numbers

Numbers without prefix are in decimal representation.

Reserved

Registers and bit fields marked with **reserved** are reserved for future use. These should be written to 0 unless otherwise stated in the Register Description. Reserved bits might be read as 1 in future devices.

Reset Value

The reset value denotes the value after reset.

Registers denoted with X have unknown value out of reset and need to be initialized before use. Note that read-modify-write operations on these registers before they are initialized results in undefined register values.

Pin Connections

Pin connections are given with a module prefix followed by a short pin name:

CMU CLKOUT1 (Clock management unit, clock output pin number 1)

The location for the pin names given in the module documentation can be found in the device-specific data sheet.

1.3 Related Documentation

Further documentation on the EFR32xG12 Wireless Gecko devices and the ARM Cortex-M4 can be found at the Silicon Labs and ARM web pages:

2. System Overview

Quick Facts

What?

The EFR32 Wireless Gecko is a highly integrated, configurable and low power wireless System-on-Chip (SoC) with a robust set of MCU and radio peripherals.

Why?

The radio enables support for zigbee, Thread, Bluetooth Low Energy (BLE) and Proprietary Protocols in 2.4 GHz and sub-GHz frequency bands while the MCU system allows customized protocols and applications to run efficiently.

How?

Dynamic or fixed packet lengths, optional address recognition, and flexible CRC and crypto schemes makes the EFR32xG12 Wireless Gecko ideal for many low power wireless IoT applications. High performance analog and digital peripherals allows complete applications to run on the EFR32xG12 Wireless Gecko SoC.

2.1 Introduction

The high level features of EFR32xG12 Wireless Gecko include:

- · High performance radio transceiver
 - · Dual-band operation
 - · Low power consumption in transmit, receive, and standby modes
 - Excellent receiver performance, including sensitivity, selectivity and blocking
 - · Excellent transmitter performance, including programmable output power, low phase noise and PA ramping
- Configurable protocol support, including standards and customer developed protocols
 - · Preamble and frame synchronization insertion in transmit and recovery in receive
 - · Flexible CRC support, including configurable polynomial and multiple CRCs for single data frames
 - · Basic address filtering performed in hardware
- · High performance, low power MCU system
 - · High Performance 32-bit ARM Cortex-M4 CPU
 - · Flexible and efficient energy management
 - · Complete set of digital peripherals
 - · Peripheral Reflex System (PRS)
 - · Precision analog interfaces
- · Low external component count
 - Fully integrated 2.4 GHz BALUN
 - · Integrated tunable crystal loading capacitors

A further introduction to the MCU and radio system is included in the following sections.

Note:

Detailed performance numbers, current consumption, pinout etc. is available in the device data sheet.

2.2 Block Diagrams

The block diagram for the EFR32xG12 Wireless Gecko System-On-Chip series is shown in (Figure 2.1 EFR32xG12 Wireless Gecko System-On-Chip Block Diagram on page 31).

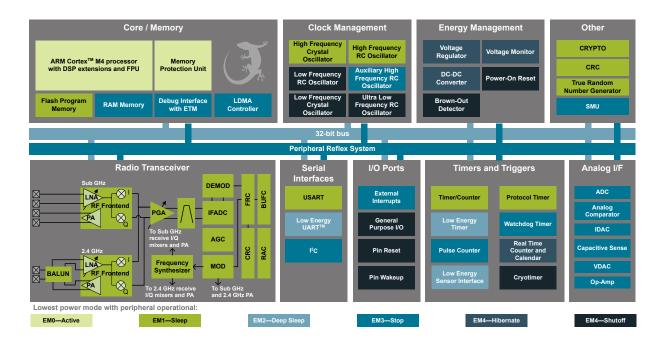

Figure 2.1. EFR32xG12 Wireless Gecko System-On-Chip Block Diagram

2.3 MCU Features Overview

· ARMCortex-M4 CPU platform

- · High Performance 32-bit processor @ up to 40 MHz
- · Memory Protection Unit
- · Wake-up Interrupt Controller

Flexible Energy Management System

- · 5 Energy Modes from EM0 to EM4 provide flexibility between higher performance and low power
- · Power routing configurations including DCDC control
- · Voltage Monitoring and Brown Out Detection
- · State Retention

· Up to 1024 KB Flash

· Read-while-write support

Up to 256 KB RAM

· Up to 65 General Purpose I/O pins

- · Configurable push-pull, open-drain, pull-up/down, input filter, drive strength
- · Configurable peripheral I/O locations
- · 16 asynchronous external interrupts
- · Output state retention and wake-up from Shutoff Mode

8 Channel DMA Controller

· Alternate/primary descriptors with scatter-gather/ping-pong operation

12 Channel Peripheral Reflex System

· Autonomous inter-peripheral signaling enables smart operation in low energy modes

• CRYPTO Advanced Encryption Standard Accelerator

- · AES encryption / decryption, with 128 or 256 bit keys
- Multiple AES modes of operation, including Counter (CTR), Galois/Counter Mode (GCM), Cipher Block Chaining (CBC), Cipher Feedback (CFB) and Output Feedback (OFB).
- Accelerated SHA-1 and SHA-2 (SHA-224 / SHA-256)
- · Accelerated Elliptic Curve Cryptography (ECC), with binary or prime fields
- Flexible 256-bit ALU and sequencer

True Random Number Generator (TRNG)

General Purpose Cyclic Redundancy Check

- · Programmable 16-bit polynomial, fixed 32-bit polynomial
- · The General Purpose Cyclic Redundancy Check (GPCRC) module comes in addition to the radio CRC

· Communication interfaces

- · 4 Universal Synchronous/Asynchronous Receiver/Transmitter
 - UART/SPI/SmartCard (ISO 7816)/IrDA/I2S
 - · Triple buffered full/half-duplex operation
 - · Hardware flow control
 - · 4-16 data bits
- 1 Low Energy UART
 - Autonomous operation with DMA in Deep Sleep Mode
- 2I²C Interface with SMBus support
 - · Address recognition in Stop Mode

· Timers/Counters

- 2 16-bit Timer/Counter
 - 3 or 4 Compare/Capture/PWM channels
 - · Dead-Time Insertion on TIMER0
- · 2 32-bit Timer/Counter
 - 3 or 4 Compare/Capture/PWM channels
 - Dead-Time Insertion on WTIMER0
- · 16-bit Low Energy Timer
- · 32-bit Ultra Low Energy Timer/Counter (CRYOTIMER) for periodic wake-up from any Energy Mode
- · 32-bit Real-Time Counter and Calendar
- · 16+16+32 bit Protocol Timer
- · 3-Channel 16-bit Pulse Counter
 - · Asynchronous pulse counting/quadrature decoding
- · 2 Watchdog Timers with dedicated RC oscillator

Ultra low power precision analog peripherals

- · 12-bit 1 Msamples/s Analog to Digital Converter
 - All APORT input channels available
 - · On-chip temperature sensor
 - · Single ended or differential operation
 - · Conversion tailgating for predictable latency
- · 12-bit 500 ksps Digital to Analog Converter
 - 2 single ended channels/1 differential channel
- · Up to 3 Operational Amplifiers
 - · Supports rail-to-rail inputs and outputs
 - · Programmable gain
- · Current Digital to Analog Converter
 - · Source or sink a configurable constant current
- 2 Analog Comparator
 - · Programmable speed/current
- · Capacitive Sense Module
 - · Supports multi-channel scan and multi-channel gang conversions
 - · Low power, fast response times
- · Analog Port

· Low-energy sensor interface

- · Autonomous sensor monitoring in deep sleep mode
- · Wide range of supported sensors, including LC sensors and capacitive touch switches
- Ultra efficient Power-on Reset and Brown-Out Detector
- · Debug Interface
 - · 4-pin Joint Test Action Group (JTAG) interface
 - · 2-pin serial-wire debug (SWD) interface
 - Embedded Trace Macrocell (ETM)

2.4 Oscillators and Clocks

EFR32xG12 Wireless Gecko has six different oscillators integrated, as shown in Table 2.1 EFR32xG12 Wireless Gecko Oscillators on page 34.

Table 2.1. EFR32xG12 Wireless Gecko Oscillators

Oscillator	Frequency	Optional?	External components	Description
HFXO	38 MHz - 40 MHz	No	Crystal	High accuracy, low jitter high frequency crystal oscillator. Tunable crystal loading capacitors are fully integrated. The HFXO is required for all types of RF communication to be active.
HFRCO	1 MHz - 38 MHz	No	-	Medium accuracy RC oscillator, typically used for timing during startup of the HFXO and as a clock source as long as no RF communication is active.
AUXHFRCO	1 MHz - 38 MHz	No	-	Medium accuracy RC oscillator, typically used as alternative clock source for Analog to Digital Converter or Debug Trace.
LFRCO	32768 Hz	No	-	Medium accuracy frequency reference typically used for medium accuracy RTCC timing.
LFXO	32768 Hz	Yes	Crystal	High accuracy frequency reference typically used for high accuracy RTCC timing. Tunable crystal loading capacitors are fully integrated.
ULFRCO	1000 Hz	No	-	Ultra low frequency oscillator typically used for the watchdog timer.

The RC oscillators can be calibrated against either of the crystal oscillators in order to compensate for temperature and voltage supply variations. Hardware support is included to measure the frequency of various oscillators against each other.

Oscillator and clock management is available through the Clock Management Unit (CMU), see section 11. CMU - Clock Management Unit for details.

2.5 RF Frequency Synthesizer

The Fractional-N RF Frequency Synthesizer (SYNTH) provides a low phase noise LO signal to be used in both receive and transmit modes.

The capabilities of the SYNTH include:

- · High performance, low phase noise
- · Fast frequency settling
- · Fast and fully automated calibration
- · Sub 100 Hz frequency resolution across the supported frequency bands

2.6 Modulation Modes

EFR32xG12 Wireless Gecko supports a wide range of modulation modes in transmit and receive:

- 2-FSK, 2-GFSK, 4-FSK, 4-GFSK, MSK, GMSK, O-QPSK with half-sine shaping, ASK / OOK, DBPSK TX
- NRZ or Manchester support
- · UART mode over air for legacy protocols
- · Data rates ranging from 600 bps up to 2 Mbps
- Configurable frequency deviation
- · Configurable Direct Sequence Spread Spectrum (DSSS), with spread sequences up to 32 chips encoding up to 4 information bits
- · Configurable 4-FSK symbol encoding

2.7 Transmit Mode

In transmit mode EFR32xG12 Wireless Gecko performs the following functionality:

- · Automatic PA power ramping during the start and end of a frame transmit
- · Programmable output power
- · Optional preamble and synchronization word insertion
- Accurate transmit frame timing to support time synchronized radio protocols
- Optional Carrier Sense Multiple Access Collision Avoidance (CSMA-CA) or Listen Before Talk (LBT) hardware support
- Integrated transmit test modes, as described in 2.17 RF Test Modes

2.8 Receive Mode

In receive mode EFR32xG12 Wireless Gecko performs the following functionality:

- A single-ended (2.4 GHz) or differential (Sub-GHz) LNA amplifies the input RF signal. The amplified signal is then mixed to a low-IF signal through the quadrature down-coversion mixer. Further signal filtering is performed before conversion to a digital signal through the I/Q ADC.
- Digitally configurable receiver bandwidth from 100 Hz to 2.5 MHz
- · Timing recovery on received data, including simultaneous support for two different frame synchronization words
- Automatic frequency offset compensation, to compensate for carrier frequency offset between the transmitter and receiver
- · Support for a wide range of modulation formats as described in section 2.6 Modulation Modes

2.9 Data Buffering

EFR32xG12 Wireless Gecko supports buffered transmit and receive modes through its buffer controller (BUFC), with four individually configurable buffers. The BUFC uses the system RAM as storage, and each buffer can be individually configured with parameters such as:

- · Buffer size
- · Buffer interrupt thresholds
- · Buffer RAM location
- · Overflow and underflow detection

In receive mode, data following frame synchronization is moved directly from the demodulator to the buffer storage.

In transmit mode, data following the inserted preamble and synchronization word is moved directly from the buffer storage to the modulator.

2.10 Unbuffered Data Transfer

For most system designs it is recommended to use the data buffering within EFR32xG12 Wireless Gecko to provide a convenient user interface.

In cases where data buffering within EFR32xG12 Wireless Gecko is not desired, it is possible to set up direct unbuffered data transfers using a single-pin or two-pin interface on EFR32xG12 Wireless Gecko. A bit clock output is provided on the Serial Clock (SC) output pin, and a serial bitstream is provided to EFR32xG12 Wireless Gecko in a transmit mode and from EFR32xG12 Wireless Gecko in a receive mode.

In unbuffered data transfer modes the hardware support provided by EFR32xG12 Wireless Gecko to perform preamble and frame synchronization insertion in transmit mode and detection in receive mode can still optionally be used.

2.11 Frame Format Support

EFR32xG12 Wireless Gecko has an extensive support for frame handling in transmit and receive modes, which allows effective handling of even advanced protocols. The support includes:

- · Preamble and frame synchronization inserted into transmitted frames
- Full frame synchronization of received frames
- Simple address matching of received frames in hardware, further configurable address and frame filtering supported through sequencer
- · Support for variable length frames
- · Automated CRC calculation and verification
- · Configurable bit ordering, with the most or least significant bit transmitted and received first

The frame format support is controlled by the Frame Controller (FRC).

2.12 Hardware CRC Support

EFR32xG12 Wireless Gecko supports a configurable CRC generation in transmit and verification in receive mode:

- 8, 16, 24 or 32 bit CRC value
- · Configurable polynomial and initialization value
- · Optional inversion of CRC value over air
- · Configurable CRC byte ordering
- Support for multiple CRC values calculated and verified per transmitted or received frame
- The CRC module is typically controlled by the Frame Controller (FRC) for in-line operations in transmit and receive modes. Alternatively, the CRC module may be accessed directly from software to calculate and verify CRC data.

2.13 Convolutional Encoding / Decoding

EFR32xG12 Wireless Gecko includes hardware support for convolutional encoding and decoding, for forward error correction (FEC). This feature is performed by the Frame Controller (FRC) module:

- · Constraint length configurable up to 7, for the highest robustness
- Configurable puncturing, to achieve rates between 1/2 rate and full rate
- · Configurable soft decision or hard decision decoding
- Convolutional coding may be used together with the symbol interleaver to improve robustness against burst errors

2.14 Binary Block Encoding / Decoding

EFR32xG12 Wireless Gecko includes hardware support for binary block encoding and decoding, both performed real-time in the transmit and receive path. This is performed in the Frame Controller (FRC) module:

The block coding works on blocks of up to 16 bits of data and adds parity bits to be capable of single or multiple bit corrections by the receiver.

- · One or more parity bits can be added and verified
- · Bit error correction
- · Lookup-codes can be used to implement virtually any block coding scheme

2.15 Data Encryption and Authentication

EFR32xG12 Wireless Gecko has hardware support for AES encryption, decryption and authentication modes. These security operations can be performed on data in RAM or any data buffer, without further CPU intervention. The key size is 128 bits.

AES modes of operations directly supported by the EFR32xG12 Wireless Gecko hardware are listed in Table 2.2 AES Modes of Operation With Hardware Support on page 37. In addition to these modes, other modes can also be implemented by using combinations of modes. For example, the CCM mode can be implemented using the CTR and CBC-MAC modes in combination.

Table 2.2. AES Modes of Operation With Hardware Support

AES Mode	Encryption / Decryption	Authentication	Comment
ECB	Yes	-	Electronic Code Book
CTR	Yes	-	Counter mode
ССМ	Yes	Yes	Counter with CBC-MAC
CCM*	Yes	Yes	CCM with encryption-only and integrity-only capabilities
GCM	Yes	Yes	Galois Counter Mode
CBC	Yes	-	Cipher Block Chaining
CBC-MAC	-	Yes	Cipher Block Chaining, Message Authentication Code
CMAC	-	Yes	Cipher-based MAC
CFB	Yes	-	Cipher Feedback
OFB	Yes	-	Output Feedback

The CRYPTO module can operate directly on data buffers provided by the BUFC module. It is also possible to provide data directly from the embedded Cortex-M4 or via DMA.

A True Random Number Generator (TRNG) module is also included for additional security. The TRNG is a non-deterministic random number generator based on a full hardware solution, and is suitable for cryptographic key generation.

2.16 Timers

EFR32xG12 Wireless Gecko includes multiple timers, as can be seen from Table 2.3 EFR32xG12 Wireless Gecko Timers Overview on page 38.

Table 2.3. EFR32xG12 Wireless Gecko Timers Overview

Timer	Number of instances	Typical clock source	Overview
RTCC	1	Low frequency (LFXO or LFRCO)	32 bit Real Time Counter and Calendar, typically used to accurately time inactive periods in the radio communication protocol and enable wakeup on compare match.
PROTIMER	1	High frequency (HFXO or HFRCO)	16+16+32 bit Protocol Timer, typically used to accurately control detailed RF protocol timing in transmit and receive modes.
TIMER	2	High frequency (HFXO or HFRCO)	16 bit general purpose timer.
WTIMER	2	High frequency (HFXO or HFRCO)	32 bit general purpose timer.
SysTick timer	1	High frequency (HFXO or HFRCO) or low frequency (LFXO, LFRCO or ULFRCO)	24-bit SysTick timer integrated in the Cortex-M4. Typically used as an Operating System timer.
WDOG	2	Low frequency (LFXO, LFRCO or ULFRCO)	Watch dog timer. Once enabled, this module must be periodically accessed. If not, this is considered an error and the EFR32xG12 Wireless Gecko is reset in order to recover the system.
LETIMER	1	Low frequency (LFXO, LFRCO or ULFRCO)	Low energy general purpose timer.

Advanced interconnect features allows synchronization between timers. This includes:

- · Start / stop any high frequency timer synchronized with the RTCC
- Trigger RSM state transitions based on compare timer compare match, for instance to provide clock cycle accuracy on frame transmit timing

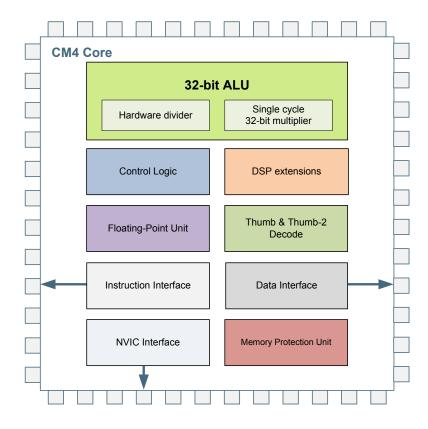

2.17 RF Test Modes

EFR32xG12 Wireless Gecko supports a wide range of RF test modes typically used for characterization and regulation compliance testing, including:

- · Unmodulated carrier transmit
- · Modulated carrier transmit, with internal configurable pseudo random data generator
- · Continuous data reception for Bit Error Rate (BER) measurements
- · Storing of raw receiver data to RAM
- · Transmit of raw frequency data from RAM

3. System Processor

Quick Facts

What?

The industry leading Cortex-M4 processor from ARM is the CPU in the EFR32xG12 Wireless Gecko devices.

Why?

The ARM Cortex-M4 is designed for exceptionally short response time, high code density, and high 32-bit throughput while maintaining a strict cost and power consumption budget.

How?

Combined with the ultra low energy peripherals available in EFR32xG12 Wireless Gecko devices, the Cortex-M4 processor's Harvard architecture, 3 stage pipeline, single cycle instructions, Thumb-2 instruction set support, and fast interrupt handling make it perfect for 8-bit, 16-bit, and 32-bit applications.

3.1 Introduction

The ARM Cortex-M4 32-bit RISC processor provides outstanding computational performance and exceptional system response to interrupts while meeting low cost requirements and low power consumption.

The ARM Cortex-M4 implemented is revision r0p1.

3.2 Features

- · Harvard architecture
 - · Separate data and program memory buses (No memory bottleneck as in a single bus system)
- · 3-stage pipeline
- · Thumb-2 instruction set
 - · Enhanced levels of performance, energy efficiency, and code density
- · Single cycle multiply and hardware divide instructions
 - · 32-bit multiplication in a single cycle
 - · Signed and unsigned divide operations between 2 and 12 cycles
- · Atomic bit manipulation with bit banding
 - · Direct access to single bits of data
 - · Two 1MB bit banding regions for memory and peripherals mapping to 32MB alias regions
 - · Atomic operation, cannot be interrupted by other bus activities
- 1.25 DMIPS/MHz
- · Memory Protection Unit
 - · Up to 8 protected memory regions
- 24 bits System Tick Timer for Real Time OS
- · Excellent 32-bit migration choice for 8/16 bit architecture based designs
 - Simplified stack-based programmer's model is compatible with traditional ARM architecture and retains the programming simplicity of legacy 8-bit and 16-bit architectures
- · Alligned or unaligned data storage and access
 - · Contiguous storage of data requiring different byte lengths
 - · Data access in a single core access cycle
- · Integrated power modes
 - · Sleep Now mode for immediate transfer to low power state
 - · Sleep on Exit mode for entry into low power state after the servicing of an interrupt
 - · Ability to extend power savings to other system components
- · Optimized for low latency, nested interrupts

3.3 Functional Description

For a full functional description of the ARM Cortex-M4 implementation in the EFR32xG12 Wireless Gecko family, the reader is referred to the ARM Cortex-M4 documentation provided by ARM.

3.3.1 Interrupt Operation

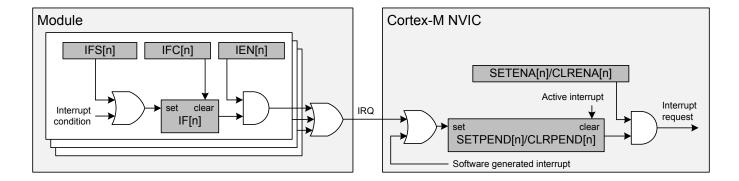

Figure 3.1. Interrupt Operation

The interrupt request (IRQ) lines are connected to the Cortex-M4. Each of these lines (shown in Table 3.1 Interrupt Request Lines (IRQ) on page 42) is connected to one or more interrupt flags in one or more modules. The interrupt flags are set by hardware on an interrupt condition. It is also possible to set/clear the interrupt flags through the IFS/IFC registers. Each interrupt flag is then qualified with its own interrupt enable bit (IEN register), before being OR'ed with the other interrupt flags to generate the IRQ. A high IRQ line will set the corresponding pending bit (can also be set/cleared with the SETPEND/CLRPEND bits in ISPR0/ICPR0) in the Cortex-M4 NVIC. The pending bit is then qualified with an enable bit (set/cleared with SETENA/CLRENA bits in ISER0/ICER0) before generating an interrupt request to the core. Figure 3.1 Interrupt Operation on page 41 illustrates the interrupt system. For more information on how the interrupts are handled inside the Cortex-M4, the reader is referred to the **ARM Cortex-M4 Technical Reference Manual**.

3.3.1.1 Avoiding Extraneous Interrupts

There can be latencies in the system such that clearing an interrupt flag could take longer than leaving an Interrupt Service Routine (ISR). This can lead to the ISR being re-entered as the interrupt flag has yet to clear immediately after leaving the ISR. To avoid this, when clearing an interrupt flag at the end of an ISR, the user should execute ARM's Data Synchronization Barrier (DSB) instruction. Another approach is to clear the interrupt flag immediately after identifying the interrupt source and then service the interrupt as shown in the pseudo-code below. The ISR typically is sufficiently long to more than cover the few cycles it may take to clear the interrupt status, and also allows the status to be checked for further interrupts before exiting the ISR.

```
irqXServiceRoutine() {
   do {
     clearIrqXStatus();
     serviceIrqX();
   } while(irqXStatusIsActive());
}
```

3.3.1.2 IFC Read-clear Operation

In addition to the normal interrupt setting and clearing operations via the IFS/IFC registers, there is an additional atomic Read-clear operation that can be enabled by setting IFCREADCLEAR=1 in the MSC_CTRL register. When enabled, reads of peripheral IFC registers will return the interrupt vector (mirroring the IF register), while at the same time clearing whichever interrupt flags are set. This operation is functionally equivalent to reading the IF register and then writing the result immediately back to the IFC register.

3.3.2 Interrupt Request Lines (IRQ)

4. Memory and Bus System

Quick Facts

What?

A low latency memory system including low energy Flash and RAM with data retention which makes the energy modes attractive.

Why?

RAM retention reduces the need for storing data in Flash and enables frequent use of the ultra low energy modes EM2 Deep Sleep and EM3 Stop.

How?

Low energy and non-volatile Flash memory stores program and application data in all energy modes and can easily be reprogrammed in system. Low leakage RAM with data retention in EM0 Active to EM3 Stop removes the data restore time penalty, and the DMA ensures fast autonomous transfers with predictable response time.

4.1 Introduction

The EFR32xG12 Wireless Gecko contains an AMBA AHB Bus system to allow bus masters to access the memory mapped address space. A multilayer AHB bus matrix connects the 5 master bus interfaces to the AHB slaves (Figure 4.1 EFR32xG12 Wireless Gecko Bus System on page 45). The bus matrix allows several AHB slaves to be accessed simultaneously. An AMBA APB interface is used for the peripherals, which are accessed through an AHB-to-APB bridge connected to the AHB bus matrix. The 5 AHB bus masters are:

- Cortex-M4 ICode: Used for instruction fetches from Code memory (valid address range: 0x00000000 0x1FFFFFFF)
- Cortex-M4 DCode: Used for debug and data access to Code memory (valid address range: 0x00000000 0x1FFFFFFF)
- Cortex-M4 System: Used for data and debug access to system space. It can access entire memory space except Code memory (valid address range: 0x20000000 0xFFFFFFFF)
- DMA: Can access the entire memory space except the internal core memory region and the DMEM code region
- Sequencer Code: Used for instruction fetches and data accesses. Instruction fetches still come from data memory. (valid address range: 0x00000000 0x0FFFFFFF, 0x20000000 0x3FFFFFF)
- Sequencer System: Can access entire memory space except internal core memory region and RAM code space (valid address range: 0x00000000 0x0FFFFFFF, 0x20000000 0xDFFFFFFF)
- BUFC: Can access general purpose SRAM (valid address range: 0x20000000 0x20FFFFFF)
- FRC: Can access general purpose SRAM (valid address range: 0x20000000 0x20FFFFFF)

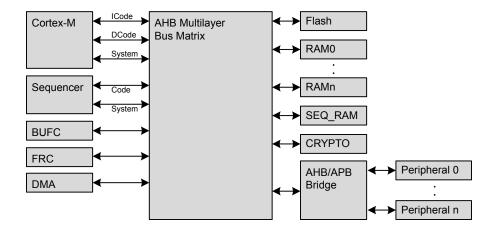

Figure 4.1. EFR32xG12 Wireless Gecko Bus System

4.2 Functional Description

The memory segments are mapped together with the internal segments of the Cortex-M4 into the system memory map shown by Figure 4.2 System Address Space With Core and Code Space Listing on page 46.

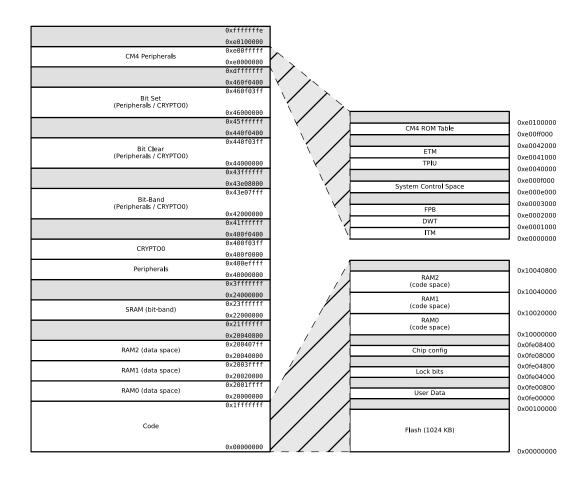

Figure 4.2. System Address Space With Core and Code Space Listing

Additionally, the peripheral address map is detailed by Figure 4.3 System Address Space With Peripheral Listing on page 47.

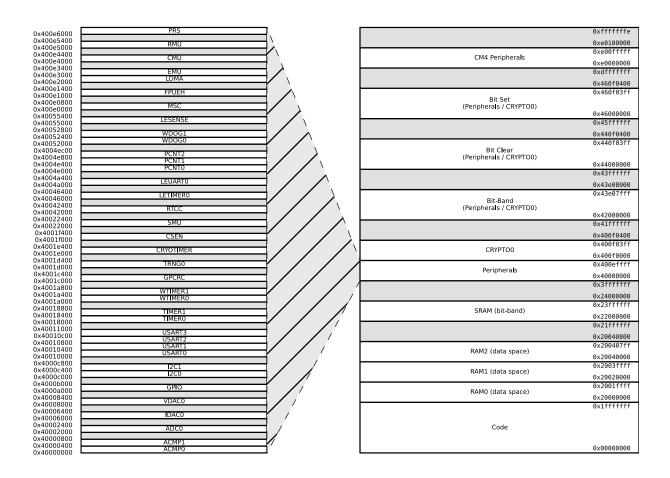

Figure 4.3. System Address Space With Peripheral Listing

The embedded SRAM is located at address 0x20000000 in the memory map of the EFR32xG12 Wireless Gecko. When running code located in SRAM starting at this address, the Cortex-M4 uses the System bus interface to fetch instructions. This results in reduced performance as the Cortex-M4 accesses stack, other data in SRAM and peripherals using the System bus interface. To be able to run code from SRAM efficiently, the SRAM is also mapped in the code space at address 0x10000000.

When running code from this space, the Cortex-M4 fetches instructions through the I/D-Code bus interface, leaving the System bus interface for data access.

The SRAM mapped into the code space can however only be accessed by the CPU and not any other bus masters, e.g. DMA. See 4.5 SRAM for more detailed info on the system SRAM.

The Sequencer RAM is used by the Sequencer for both instructions and data. This RAM is also available for general use by most AHB masters.

4.2.1 Peripheral Non-Word Access Behavior

When writing to peripheral registers, all accesses are treated as 32-bit accesses. This means that writes to a register need to be large enough to cover all bits of register, otherwise, any uncovered bits may become corrupted from the partial-word transfer. Thus, the safest practice is to always do 32-bit writes to peripheral registers.

When reading, there is generally no issue with partial word accesses, however, note that any read action (e.g. FIFO popping) will be triggered regardless of whether the actual FIFO bit-field was included in the transfer size.

Note: The implementation of bit-banding in the core is such that bit-band accesses forward the transfer size info into the actual bus transfer size, so the same restrictions apply to bit-band accesses as apply to normal read/write accesses.

4.2.2 Bit-banding

The SRAM bit-band alias and peripheral bit-band alias regions are located at 0x22000000 and 0x42000000 respectively. Read and write operations to these regions are converted into masked single-bit reads and atomic single-bit writes to the embedded SRAM and peripherals of the EFR32xG12 Wireless Gecko.

Note: Bit-banding is only available through the CPU. No other AHB masters (e.g. DMA) can perform Bit-banding operations.

Using a standard approach to modify a single register or SRAM bit in the aliased regions, would require software to read the value of the byte, half-word or word containing the bit, modify the bit, and then write the byte, half-word or word back to the register or SRAM address. Using bit-banding, this can be done in a single operation, consuming only two bus cycles. As read-writeback, bit-masking and bit-shift operations are not necessary in software, code size is reduced and execution speed improved.

The bit-band regions allow each bit in the SRAM and Peripheral areas of the memory map to be addressed. To set or clear a bit in the embedded SRAM, write a 1 or a 0 to the following address:

bit_address = 0x22000000 + (address - 0x20000000) · 32 + bit · 4

where address is the address of the 32-bit word containing the bit to modify, and bit is the index of the bit in the 32-bit word.

To modify a bit in the Peripheral area, use the following address:

bit address = $0x42000000 + (address - 0x40000000) \cdot 32 + bit \cdot 4$

4.2.3 Peripheral Bit Set and Clear

The EFR32xG12 Wireless Gecko supports bit set and bit clear access to all peripherals except those listed in Table 4.1 Peripherals that Do Not Support Bit Set and Bit Clear on page 49. The bit set and bit clear functionality (also called Bit Access) enables modification of bit fields (single bit or multiple bit wide) without the need to perform a read-modify-write (though it is functionally equivalent). Also, the operation is contained within a single bus access (for HF peripherals), unlike the Bit-banding operation described in section 4.2.2 Bit-banding which consumes two bus accesses per operation. All AHB masters can utilize this feature.

The bit clear aliasing region starts at 0x44000000 and the bit set aliasing region starts at 0x46000000. Thus, to apply a bit set or clear operation, write the bit set or clear mask to the following addresses:

```
bit_clear_address = address + 0x04000000
bit_set_address = address + 0x06000000
```

For bit set operations, bit locations that are 1 in the bit mask will be set in the destination register:

```
register = (register OR mask)
```

For bit clear operations, bit locations that are 1 in the bit mask will be cleared in the destination register:

```
register = (register AND (NOT mask))
```

Note: It is possible to combine bit clear and bit set operations in order to arbitrarily modify multi-bit register fields, without affecting other fields in the same register. In this case, care should be taken to ensure that the field does not have intermediate values that can lead to erroneous behavior. For example, if bit clear and bit set operations are used to change an analog tuning register field from 25 to 26, the field would initially take on a value of zero. If the analog module is active at the time, this could lead to undesired behavior.

The peripherals listed in Table 4.1 Peripherals that Do Not Support Bit Set and Bit Clear on page 49 do not support Bit Access for any registers. All other peripherals do support Bit Access, however, there may be cases of certain registers that do not support it. Such registers have a note regarding this lack of support.

4.2.5 Bus Matrix

The Bus Matrix connects the memory segments to the bus masters as detailed in 4.1 Introduction.

4.2.5.1 Arbitration

The Bus Matrix uses a round-robin arbitration algorithm which enables high throughput and low latency, while starvation of simultaneous accesses to the same bus slave are eliminated. Round-robin does not assign a fixed priority to each bus master. The arbiter does not insert any bus wait-states during peak interaction. However, one wait state is inserted for master accesses occurring after a prolonged inactive time. This wait state allows for increased power efficiency during master idle time.

4.2.5.2 Peripheral Access Performance

The Bus Matrix is a multi-layer energy optimized AMBA AHB compliant bus with an internal bandwidth of 5x a single AHB interface.

The Cortex-M4, DMA Controller, and peripherals (not peripherals in the low frequency clock domain) run on clocks which can be prescaled separately. Clocks and prescaling are described in more detail in 11. CMU - Clock Management Unit . This section describes the expected bus wait states for a peripheral based on its frequency relative to the HFCLK frequency. For this discussion, PERCLK refers to a selected peripheral's clock frequency, which is some integer division of the HFCLK frequency.

4.2.5.2.1 WS0 Mode

In general, when accessing a peripheral, the latency in number of HFCLK cycles, not including master arbitration, is given by:

 $N_{bus\ cycles} = N_{slave\ cycles} \cdot f_{HFCLK}/f_{PERCLK}, \ best-case\ write\ accesses$ $N_{bus\ cycles} = N_{slave\ cycles} \cdot f_{HFCLK}/f_{PERCLK} + 1, \ best-case\ read\ accesses$ $N_{bus\ cycles} = (N_{slave\ cycles} + 1) \cdot f_{HFCLK}/f_{PERCLK} - 1, \ worst-case\ write\ accesses$ $N_{bus\ cycles} = (N_{slave\ cycles} + 1) \cdot f_{HFCLK}/f_{PERCLK}, \ worst-case\ read\ accesses$

where N_{slave cycles} is the throughput of the slave's bus interface in number of PERCLK cycles per transfer, including any wait cycles introduced by the slave.

Figure 4.4. Bus Access Latency (General Case)

Note that a latency of ${\bf 1}$ cycle corresponds to ${\bf 0}$ wait states.

Additionally, for back-to-back accesses to the same peripheral, the throughput in number of cycles per transfer is given by:

 $N_{bus\ cycles} = N_{slave\ cycles} \cdot f_{HFCLK}/f_{PERCLK}$, write accesses $N_{bus\ cycles} = (N_{slave\ cycles} + 1) \cdot f_{HFCLK}/f_{PERCLK}$, read accesses

Figure 4.5. Bus Access Throughput (Back-to-Back Transfers)

Lastly, in the highest performing case, where PERCLK equals HFCLK and the slave does not introduce any additional wait states, the access latency in number of cycles is given by:

N_{bus cycles} = 1, write accesses N_{bus cycles} = 2, read accesses

Figure 4.6. Bus Access Latency (Max Performance)

4.2.5.2.2 WS1 Mode

In general, when accessing a peripheral, the latency in number of HFCLK cycles, not including master arbitration, is given by:

$$\begin{split} N_{bus\ cycles} &= N_{slave\ cycles} \cdot f_{HFCLK}/f_{PERCLK} + 2,\ best-case\ write\ accesses \\ N_{bus\ cycles} &= N_{slave\ cycles} \cdot f_{HFCLK}/f_{PERCLK} + 1,\ best-case\ read\ accesses \\ N_{bus\ cycles} &= (N_{slave\ cycles} + 1) \cdot f_{HFCLK}/f_{PERCLK} + 1,\ worst-case\ write\ accesses \\ N_{bus\ cycles} &= (N_{slave\ cycles} + 1) \cdot f_{HFCLK}/f_{PERCLK},\ worst-case\ read\ accesses \end{split}$$

where N_{slave cycles} is the throughput of the slave's bus interface in number of PERCLK cycles per transfer, including any wait cycles introduced by the slave.

Figure 4.7. Bus Access Latency (General Case)

Note that a latency of ${\bf 1}$ cycle corresponds to ${\bf 0}$ wait states.

Additionally, for back-to-back accesses to the same peripheral, the throughput in number of cycles per transfer is given by:

$$\begin{split} N_{bus\ cycles} &= max\{f_{HFCLK}/f_{PERCLK},\ 2\} + N_{slave\ cycles} \cdot f_{HFCLK}/f_{PERCLK},\ write\ accesses \\ N_{bus\ cycles} &= (N_{slave\ cycles} + 1) \cdot f_{HFCLK}/f_{PERCLK},\ read\ accesses \end{split}$$

Figure 4.8. Bus Access Throughput (Back-to-Back Transfers)

Lastly, in the highest performing case, where PERCLK equals HFCLK and the slave does not introduce any additional wait states, the access latency in number of cycles is given by:

 $N_{\text{bus cycles}} = 3$, write accesses $N_{\text{bus cycles}} = 2$, read accesses

Figure 4.9. Bus Access Latency (Max Performance)

4.2.5.2.3 Core Access Latency

Note that the cycle counts in the equations above is in terms of the HFCLK. When the core is prescaled from the bus clock, the core will see a reduced number of latency cycles given by:

 $N_{core\ cycles}$ = ceiling($N_{bus\ cycles} \cdot f_{HFCORECLK}/f_{HFCLK}$) where master arbitration is not included.

Figure 4.10. Core Access Latency

4.2.5.3 Bus Faults

System accesses from the core can receive a bus fault in the following condition(s):

- The core attempts to access an address that is not assigned to any peripheral or other system device. These faults can be enabled or disabled by setting the ADDRFAULTEN bit appropriately in MSC_CTRL.
- The core attempts to access a peripheral or system device that has its clock disabled. These faults can be enabled or disabled by setting the CLKDISFAULTEN bit appropriately in MSC_CTRL.
- The bus times out during an access. For example, this could happen while trying to synchronize volatile read data during an LE
 peripheral access. See 11.3.1.1 HFCLK High Frequency Clock. These faults can be enabled or disabled by setting the TIMEOUTFAULTEN bit appropriately in MSC CTRL.

In addition to any condition-specific bus fault control bits, the bus fault interrupt itself can be enabled or disabled in the same way as all other internal core interrupts.

Note: The icache flush is not triggered at the event of a bus fault. As a result, when an instruction fetch results in a bus fault, invalid data may be cached. This means that the next time the instruction that caused the bus fault is fetched, the processor core will get the invalid cached data without any bus fault. In order to avoid invalid cached data propagation to the processor core, software should manually invalidate cache by writing 1 to MSC_CMD_INVCACHE bitfield at the event of a bus fault.

4.3 Access to Low Energy Peripherals (Asynchronous Registers)

The Low Energy Peripherals are capable of running when the high frequency oscillator and core system is powered off, i.e. in energy mode EM2 Deep Sleep and in some cases also EM3 Stop. This enables the peripherals to perform tasks while the system energy consumption is minimal.

The Low Energy Peripherals are listed in Table 4.3 Low Energy Peripherals on page 50.

All Low Energy Peripherals are memory mapped, with automatic data synchronization. Because the Low Energy Peripherals are running on clocks asynchronous to the high frequency system clock, there are some constraints on how register accesses are performed, as described in the following sections.

4.3.1 Writing

Every Low Energy Peripheral has one or more registers with data that needs to be synchronized into the Low Energy clock domain to maintain data consistency and predictable operation. There are two different synchronization mechanisms on the EFR32, immediate synchronization, and delayed synchronization. Immediate synchronization is available for the RTCC, LESENSE and LETIMER, and results in an immediate update of the target registers. Delayed synchronization is used for the remaining Low Energy Peripherals, and for these peripherals, a write operation requires 3 positive edges of the clock on the Low Energy Peripheral being accessed. Registers requiring synchronization are marked "Async Reg" in their description header.

Note: On the Gecko series of devices, all LE peripherals are subject to delayed synchronization.

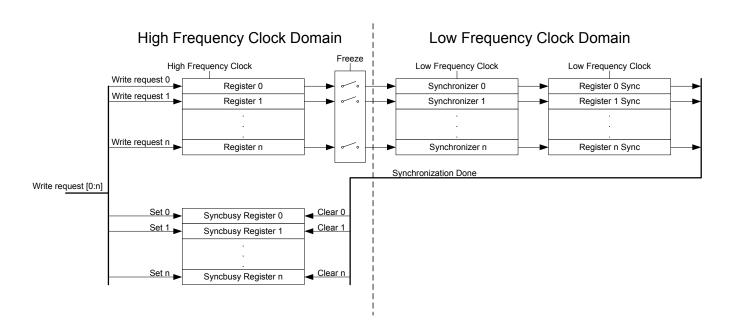

Figure 4.11. Write Operation to Low Energy Peripherals

4.3.1.1 Delayed Synchronization

After writing data to a register which value is to be synchronized into the Low Energy Peripheral using delayed synchronization, a corresponding busy flag in the <module_name>_SYNCBUSY register (e.g. LETIMER_SYNCBUSY) is set. This flag is set as long as synchronization is in progress and is cleared upon completion.

Note: Subsequent writes to the same register before the corresponding busy flag is cleared is not supported. Write before the busy flag is cleared may result in undefined behavior. In general the SYNCBUSY register only needs to be observed if there is a risk of multiple write access to a register (which must be prevented). It is not required to wait until the relevant flag in the SYNCBUSY register is cleared after writing a register. E.g., EM2 Deep Sleep can be entered directly after writing a register.

See Figure 4.12 Write Operation to Low Energy Peripherals on page 56 for an overview of the writing mechanism operation.

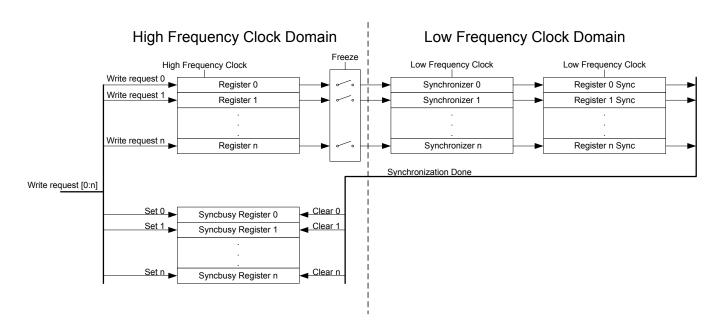

Figure 4.12. Write Operation to Low Energy Peripherals

4.3.1.2 Immediate Synchronization

In contrast to the peripherals with delayed synchronization, peripherals with immediate synchronization do not experience a register write delay for most registers. Registers are updated immediately on the peripheral write access. If such a write is done close to an edge on the clock of the peripheral, the write can be delayed until after that clock edge. This will introduce wait-states on the peripheral access.

One exception is made for commands (writing to the CMD register) in peripherals with immediate synchronization. Peripherals with immediate synchronization each have a SYNCBUSY register with a bit for the CMD register status. Commands written to a peripheral with immediate synchronization are not executed before the first peripheral clock after the write. In this period, the SYNCBUSY flag for the command register is set, indicating that the command has not yet been performed.

To maintain compatibility with earlier Gecko series, the SYNCBUSY register reserves placeholders where other register synchronization bits resided. These bits always read 0, indicating that register writes are always safe.

Note: If compatibility with earlier Gecko series is a requirement for a given application, the rules that apply to delayed synchronization with respect to SYNCBUSY should also be followed for the peripherals that support immediate synchronization.

4.3.2 Reading

When reading from a Low Energy Peripheral, the data read is synchronized regardless if it originates in the Low Energy clock domain or High Frequency clock domain. See Figure 4.13 Read Operation From Low Energy Peripherals on page 57 for an overview of the reading operation.

Note: Writing a register and then immediately reading the new value of the register may give the impression that the write operation is complete. This may not be the case. Refer to the SYNCBUSY register for correct status of the write operation to the Low Energy Peripheral.

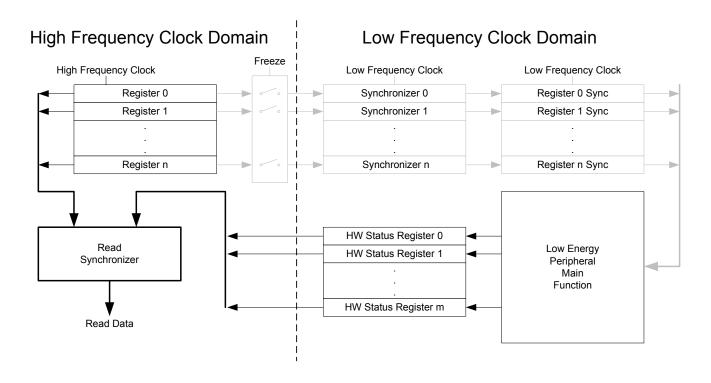

Figure 4.13. Read Operation From Low Energy Peripherals

4.3.3 FREEZE Register

In all Low Energy Peripheral with delayed synchronization there is a <module_name>_FREEZE register (e.g. RTCC_FREEZE). The register contains a bit named REGFREEZE. If precise control of the synchronization process is required, this bit may be utilized. When REGFREEZE is set, the synchronization process is halted allowing the software to write multiple Low Energy registers before starting the synchronization process, thus providing precise control of the module update process. The synchronization process is started by clearing the REGFREEZE bit.

Note: The FREEZE register is also present on peripherals with immediate synchronization, but there it has no effect

4.4 Flash

The Flash retains data in any state and typically stores the application code, special user data and security information. The Flash memory is typically programmed through the debug interface, but can also be erased and written to from software.

- Up to 1024 KB of memory
- · Page size of 2 KB (minimum erase unit)
- · Minimum 10K erase cycles endurance
- Application code area organized as two equal-sized banks with bank address swap capabilites.
- · Greater than 10 years data retention at 85 °C
- · Lock-bits for memory protection
- · Data retention in any state

4.5 SRAM

The primary task of the SRAM memory is to store application data. Additionally, it is possible to execute instructions from SRAM, and the DMA may be set up to transfer data between the SRAM, flash and peripherals.

- · Up to 256 KB of memory
- · Bit-band access support
- · Set of RAM blocks may be powered down when not in use
- Data retention of the entire memory in EM0 Active to EM3 Stop

The SRAM memory may be split among two or more different AHB slaves (e.g., RAM0, RAM1, ...) in order to allow simultaneous access to different sections of the memory from two different AHB masters. For example, the Cortex-M4 can access RAM0 while the DMA controller accesses RAM1 in parallel. See 4.1 Introduction for AHB slave connectivity details.

Note: The individual RAM sections may be smaller on some parts, however, the RAM AHB slaves maintain a contiguous address map. For example, if RAM0 is half-size on a part, then RAM1 is relocated to begin immediately after RAM0's last address. Using the provided software header files and linker scripts allows handling of this remapping in an autonomous manner.

4.6 DI Page Entry Map

The DI page contains production calibration data as well as device identification information. See the peripheral chapters for how each calibration value is to be used with the associated peripheral.

The offset address is relative to the start address of the DI page (see 7.3 Functional Description).

5. Radio Transceiver

Quick Facts

What?

The Radio Transceiver provides access to transmit and receive data, radio settings and control interface.

Why?

The Radio Transceiver enables the user to communicate using a wide range of data rates, modulation and frame formats.

How?

Dynamic or fixed frame lengths, optional address recognition, flexible CRC and crypto schemes makes the EFR32 perfectly suit any application using low or medium data rate radio communication.

5.1 Introduction

The Radio Transceiver of the EFR32 enables the user to control a wide range of settings and options for tailoring radio operation precisely to the users need. It provides access to the transmit and receive data buffers and supports both dynamic and static frame lengths, as well as automatic address filtering and CRC insertion/verification.

As seen in the Radio Overview illustration (Figure 5.1 Radio Overview on page 129), the radio consists of several modules all responsible for specific tasks. Please refer to the abbreviations section (Appendix 1. Abbreviations) for a comprehensive description of acronyms.

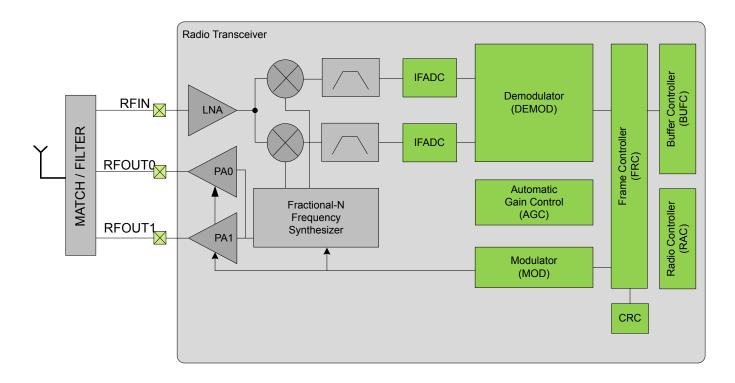

Figure 5.1. Radio Overview

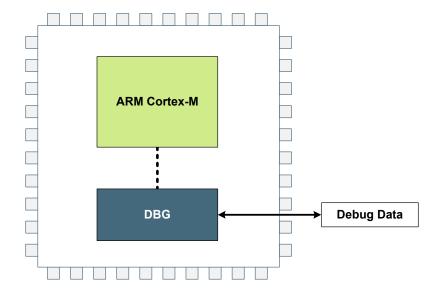

During transmission (TX), the Radio Controller enables the SYNTH, Modulator and PA. The Modulator requests data from the Frame Controller, which reads data from a buffer. Based upon modulation format and data to send, the Modulator manipulates the SYNTH to output the correct frequency and phase. When the whole frame has been transmitted, the radio can automatically switch to receive mode.

In receive mode (RX), the radio controller enables the LNA, SYNTH, Mixer, ADC and Demodulator. The Demodulator searches for valid frames according to modulation format and data rate. If a frame is detected, the demodulated data is handed to the Frame Controller, which stores the data in the Buffer. When the complete frame has been received (determined by the Frame Controller), it is possible to either go to TX or stay in RX to search for a new frame.

The Radio Transceiver interface is accessible through software drivers provided by Silicon Labs.

6. DBG - Debug Interface

Quick Facts

What?

The Debug Interface is used to program and debug EFR32xG12 Wireless Gecko devices.

Why?

The Debug Interface makes it easy to re-program and update the system in the field, and allows debugging with minimal I/O pin usage.

How?

The Cortex-M4 supports advanced debugging features. EFR32xG12 Wireless Gecko devices can use a minimum of two port pins for debugging or programming. The internal and external state of the system can be examined with debug extensions supporting instruction or data access break and watch points.

6.1 Introduction

The EFR32xG12 Wireless Gecko devices include hardware debug support through a 2-pin serial-wire debug (SWD) interface or a 4-pin Joint Test Action Group (JTAG) interface, as well as an Embedded Trace Module (ETM) for data/instruction tracing.

For more technical information about the debug interface the reader is referred to:

- · ARM Cortex-M4 Technical Reference Manual
- · ARM CoreSight Components Technical Reference Manual
- ARM Debug Interface v5 Architecture Specification
- IEEE Standard for Test Access Port and Boundary-Scan Architecture, IEEE 1149.1-2013

6.2 Features

- · Debug Access Port Serial Wire JTAG (DAP SWJ-DP)
 - Implements the ADIv5 debug interface
- Authentication Access Point (AAP)
 - · Implements various user commands
- · Flash Patch and Breakpoint (FPB) unit
 - · Implement breakpoints and code patches
- · Data Watch point and Trace (DWT) unit
 - · Implement watch points, trigger resources and system profiling
- Instrumentation Trace Macrocell (ITM)
 - · Application-driven trace source that supports printf style debugging
- Embedded Trace Macrocell v3.5 (ETM)
 - · Real time instruction and data trace information of the processor

6.3 Functional Description

Operation of the available debug interface is described in the following sections.

6.3.1 Debug Pins

The following pins are the debug connections for the device:

- Serial Wire Clock Input and Test Clock Input (SWCLKTCK): This pin is enabled after power-up and has a built-in pull down.
- Serial Wire Data Input/Output and Test Mode Select Input (SWDIOTMS): This pin is enabled after power-up and has a built-in pull-up.
- Test Data Output (TDO): This pin is assigned to JTAG functionality after power-up. However, it remains in high-Z state until the first valid JTAG command is received.
- Test Data Input (TDI): This pin is assigned to JTAG functionality after power-up. However, it remains in high-Z state until the first valid JTAG command is received. Once enabled, the pin has a built-in pull-up.

The debug pins have pull-down and pull-up enabled by default, so leaving them enabled may increase the current consumption if left connected to supply or ground. The debug pins can be enabled and disabled through GPIO_ROUTEPEN, see 32.3.4.2.3 Disabling Debug Connections. Remember that upon disabling the debug pins, debug contact with the device is lost once the DAP SWJ-DP power request bits are deasserted. By default after power cycle the part's debug pins are in JTAG mode. If during debugging session the pins are switched to SWD mode, a power cycle is required to bring restore the pins to JTAG mode.

6.3.2 Embedded Trace Macrocell V3.5 (ETM)

The ETM makes it possible to trace both instruction and data from the processor in real time. The trace can be controlled through a set of triggering and filtering resources. The resources include 4 address comparators, 2 data value comparators, 2 counters, a context ID comparator and a sequencer. The ETM circuit does not automatically enable an auxiliary clock. If AUXCLK is elected as the ETM clock source, the AUXHFRCO oscillator must be enabled by setting AUXHFRCOEN in CMU_OSCENCMD before enabling the ETM. Likewise, if switching from AUXCLK to a different source for ETM, the AUXHFRCO must remain enabled until the clock switch has completed.

The trace can be exported through a set of trace pins, which include:

- Trace Clock (TCLK): Functions as a sample clock for the trace. This pin is disabled after reset.
- Trace Data 0 Trace Data 3 (TD0-TD3): The data pins provide the compressed trace stream. These pins are disabled after reset.

For information on how to configure the ETM, see the ARM Embedded Trace Macrocell Architecture Specification. The Trace Clock and Trace Data pins can be enabled through the GPIO. For more information on how to enable the ETM Trace pins, the reader is referred to 32.3.4.2.4 ETM Trace Connections.

6.3.3 Debug and EM2 Deep Sleep/EM3 Stop

Leaving the debugger connected when issuing a WFI or WFE to enter EM2 Deep Sleep or EM3 Stop will make the system enter a special EM2 Deep Sleep. This mode differs from regular EM2 Deep Sleep and EM3 Stop in that the high frequency clocks are still enabled, and certain core functionality is still powered in order to maintain debug-functionality. Because of this, the current consumption in this mode is closer to EM1 Sleep and it is therefore important to deassert the power requests in the DAP SWJ-DP and disconnect the debugger before doing current consumption measurements.

6.3.4 Authentication Access Point

The Authentication Acces Point (AAP) is a set of registers that provide a minimal amount of debugging and system level commands. The AAP registers contain commands to issue a FLASH erase, a system reset, a CRC of user code pages, and stalling the system bus. The user must program the APSEL bit field to 255 inside of the ARM DAP SWJ Debug Port SELECT register to access the AAP. The AAP is only accessible from a debugger and not from the core.

6.3.4.1 System Bus Stall

The system bus can be stalled at any time using the SYSBUSSTALL register bit. Once the SYSBUSSTALL is set, the system bus will remain stalled until SYSBUSSTALL is cleared. While the system bus is stalled, only the registers inside the Cortex-M4, AAP and the debugger can be accessed. The SYSBUSSTALL register is available at all times through the AAP.

6.3.4.2 Command Key

The AAP uses a command key to enable the DEVICEERASE and SYSRESETREQ AAP commands. The command key must be written with the correct key in order for the commands to execute.

6.3.4.3 Device Erase

The device can be erased by stalling the system bus, writing AAP_CMDKEY, and then writing the DEVICEERASE register bit. Upon writing the command bit, the ERASEBUSY bit is asserted. The ERASEBUSY bit will be de-asserted once the erase is complete. The SYSRESETREQ bit must then be set to resume a normal debugger session. The DEVICEERASE register is available at all times through the AAP once the CMDKEY is entered.

6.3.4.4 System Reset

The system can be reset by writing AAP_CMDKEY followed by writing the SYSRESTREQ register bit. This must be done after asserting DEVICEERASE or CRCREQ. Depending on the reset level setting for system reset, asserting SYSRESETREQ will either reset the entire AAP register space or just the SYSRESETREQ bit. See 9.3.1 Reset Levels for more details on reset levels. The SYSRESETREQ register is available at all times through the AAP once the CMDKEY is enetered.

6.3.4.5 User Flash Page CRC

The CRCREQ command initiates a CRC calculation on a given Flash Page. The CRC is only available on the Main, User Data, and Lock Bit pages. It is highly recommended that the system bus is stalled before any CRCREQ commands are issued. The CRC calculation uses the on chip CRC block configured in 32 bit CRC mode. The Flash Page address for the CRCREQ command is written to the CRCADDR register. After issuing the CRCREQ, the CRCBUSY flag is asserted. Once the CRCBUSY flag is de-asserted, the resulting page CRC can be found in the CRCRESULT register. Once issuing a CRC command, the CPU is stalled and remains stalled until a system reset occurs. Multiple CRC requests can occur before resetting the system. However, a CRC request that occurs while the CRCBUSY flag is asserted will be ignored. The CRC registers are available at all times through the AAP, even when the device is debug locked.

6.3.5 Debug Lock

The debug access to the Cortex-M4 is locked by clearing the Debug Lock Word (DLW) and resetting the device, see 7.3.2 Lock Bits (LB) Page Description.

When debug access is locked, the debugger can access the DAP SWJ-DP and AAP registers. However, the connection to the Cortex-M4 core and the whole bus-system is blocked. This mechanism is controlled by the Authentication Access Port (AAP) as illustrated by Figure 6.1 AAP - Authentication Access Port on page 132.

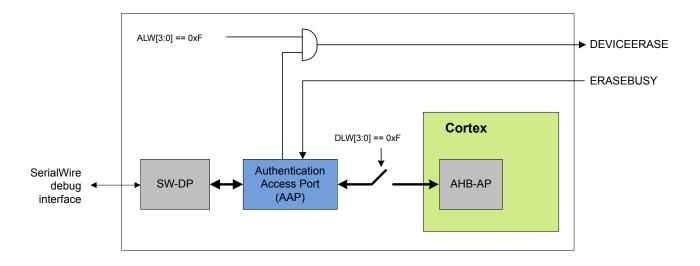

Figure 6.1. AAP - Authentication Access Port

If the DLW is cleared, the device is locked. If the device is locked and the the AAP Lock Word (ALW) has not been cleared, it can be unlocked by writing a valid key to the AAP_CMDKEY register and then setting the DEVICEERASE bit of the AAP_CMD register via the debug interface. This operation erases the main block of flash, clears all lock bits, and debug access to the Cortex-M4 and bus-system is enabled. The operation takes tens of mili seconds to complete. Note that the SRAM contents will also be deleted during a device erase, while the UD-page is not erased.

The debugger may read the status of the device erase from the AAP_STATUS register. When the ERASEBUSY bit is set low after DEVICEERASE of the AAP_CMD register is set, the debugger may set the SYSRESETREQ bit in the AAP_CMD register. After reset, the debugger may resume a normal debug session through the AHB-AP.

6.3.6 AAP Lock

Take extreme caution when using this feature. Once the AAP has been locked, the state of the FLASH can not be changed via the debugger.

6.3.7 Debugger Reads of Actionable Registers

Some peripheral registers cause particular actions when read, e.g FIFOs which pop and IFC registers which clear the IF flags when read. This can cause problems when debugging and the user wants to read the value without triggering the read action. For this reason, by default, the peripherals will not execute these triggered actions when an attached debugger is performing the read accesses through the AAP. To override this behavior, the debugger can configure the MASTERTYPE bitfield of the Cortex-M4 AHB Access Port CSW register in order to emulate a core access when performing system bus transfers.

Note:

Registers with actionable reads are noted in their register descriptions. Refer to Table 1.1 Register Access Types on page 28.

6.3.8 Debug Recovery

Debug recovery is the ability to stall the system bus before the Cortex-M4 executes code. For example, the first few instructions may disconnect the debugger pins. When this occurs it is difficult to connect the debugger and halt the Cortex-M4 before the Cortex-M4 starts to execute. By holding down pin reset, issuing the System Bus Stall AAP instruction, then releasing pin reset, the debugger can stall the system bus before the Cortex-M4 has a chance to execute. Because the system is under reset during this procedure the Debugger can not look for ACK's from the part. Once the system bus is stalled, the FLASH can be erased by issuing the AAP_CMDKEY and then the writting the DEVICEERASE in the AAP_CMD register.

6.4 Register Map

The offset register address is relative to the registers base address.

Offset	Name	Туре	Description
0x000	AAP_CMD	W1	Command Register

7. MSC - Memory System Controller

011001010110111001100101011110010

Quick Facts

What?

The user can perform flash memory read, read configuration and write operations through the Memory System Controller (MSC).

Why?

The MSC allows the application code, user data and flash lock bits to be stored in non-volatile flash memory. Certain memory system functions, such as program memory wait-states and bus faults are also configured from the MSC peripheral register interface, giving the developer the ability to dynamically customize the memory system performance, security level, energy consumption and error handling capabilities to the requirements at hand.

How?

The MSC enables minimum energy consumption by integrating low-energy flash with a charge pump so that a dedicated external supply is not needed for program and erase operations. An easy to use write and erase interface is supported by an internal, fixed-frequency oscillator and automated flash timing and control logic that reduces software complexity without using other timer resources.

Application code may dynamically scale between high energy optimization and high code execution performance through advanced read modes.

A highly efficient instruction cache reduces the number of flash reads significantly, thus saving energy. This holds true even at high operating frequencies because instruction cache hits eliminate otherwise necessary wait states. Built-in performance counters can be used to measure the efficiency of the instruction cache.

7.1 Introduction

The Memory System Controller (MSC) is the program memory unit of the EFR32xG12 Wireless Gecko microcontroller. The flash memory is readable and writable from both the Cortex-M4 and DMA. The flash memory is divided into two blocks; the main block and the information block. Program code is normally written to the main block. Additionally, the information block is available for special user data and flash lock bits. There is also a read-only page in the information block containing system and device calibration data. Read and write operations are supported in the energy modes EM0 Active and EM1 Sleep.

7.2 Features

- · AHB read interface
 - · Scalable access performance to optimize the Cortex-M4 code interface
 - Zero wait-state access up to 25 MHz
 - · Advanced energy optimization functionality
 - Conditional branch target prefetch suppression
 - · Cortex-M4 disfolding of if-then (IT) blocks
 - · Instruction Cache
 - · DMA read support in EM0 Active and EM1 Sleep
- · Command and status interface
 - · Flash write and erase
 - · Accessible from Cortex-M4 in EM0 Active
 - DMA write support in EM0 Active and EM1 Sleep
 - · Read-while-write support on parts with 512 kB or more flash
 - · Core clock independent flash timing
 - · Internal oscillator and internal timers for precise and autonomous flash timing
 - · General purpose timers are not occupied during flash erase and write operations
 - · Configurable interrupt erase abort
 - · Improved interrupt predictability
 - · Memory and bus fault control
- · Security features
 - · Lockable debug access
 - · Page lock bits
 - · SW mass erase lock bits
 - · Authentication Access Port (AAP) lock bits
- · End-of-write and end-of-erase interrupts

7.3 Functional Description

The size of the main block is device dependent. The largest size available is 1024 KB (512 pages). The information block has 2 KB available for user data. The information block also contains chip configuration data located in a reserved area. The main block is mapped to address 0x000000000 and the information block is mapped to address 0x0FE00000. Table 7.1 MSC Flash Memory Mapping on page 141 outlines how the flash is mapped in the memory space. All flash memory is organized into 2 KB pages.

Table 7.1. MSC Flash Memory Mapping

Block	Page	Base address	Write/Erase by	Software Reada- ble?	Purpose/Name	Size
Main ¹	0	0x00000000	Software, debug	Yes	User code and data	256 KB - 1024

Note:

7.3.1 User Data (UD) Page Description

This is the user data page in the information block. The page can be erased and written by software. The page is erased by the ERA-SEPAGE command of the MSC_WRITECMD register. Note that the page is not erased by a device erase operation. The device erase operation is described in 6.3.4 Authentication Access Point.

^{1.} Block/page erased by a device erase.

7.3.2 Lock Bits (LB) Page Description

This page contains the following information:

- · Main block Page Lock Words (PLWs)
- User data page Lock Word (ULWs)
- Debug Lock Word (DLW)
- Mass erase Lock Word (MLW)
- Authentication Access Port (AAP) lock word (ALW)
- Bank switch disable (CLW1)
- · Bootloader enable (CLW0)
- · Pin reset soft (CLW0)

The words in this page are organized as shown in Table 7.2 Lock Bits Page Structure on page 142:

Table 7.2. Lock Bits Page Structure

127	DLW
126	ULW
125	MLW
124	ALW
123	CLW1
122	CLW0
N	PLW[N]
1	PLW[1]
0	PLW[0]

There are 32 page lock bits per page lock word (PLW). Bit 0 refers to the first page and bit 31 refers to the last page within a PLW. Thus, PLW[0] contains lock bits for page 0-31 in the main block, PLW[1] contains lock bits for page 32-63 etc. A page is locked when the bit is 0. A locked page cannot be erased or written.

Word 127 is the debug lock word (DLW). The four LSBs of this word are the debug lock bits. If these bits are 0xF, then debug access is enabled. Debug access to the core is disabled from power-on reset until the DLW is evaluated immediately before the Cortex-M4 starts execution of the user application code. If the bits are not 0xF, then debug access to the core remains blocked.

Word 126 is the user page lock word (ULW). Bit 0 of this word is the User Data Page lock bit. Bit 1 in this word locks the Lock Bits Page. The lock bits can be reset by a device erase operation initiated from the Authentication Access Port (AAP) registers. The AAP is described in more detail in 6.3.4 Authentication Access Point. Note that the AAP is only accessible from the debug interface, and cannot be accessed from the Cortex-M4 core.

Word 125 is the mass erase lock word (MLW). For devices that support read-while-write, bit 0 locks the lower half of the flash, preventing mass erase, and bit 1 locks the upper half of the flash. For devices that do not support read-while-write, bit 0 locks the entire flash. The mass erase lock bits will not have any effect on device erases initiated from the Authenitiation Access Port (AAP) registers. The AAP is described in more detail in 6.3.4 Authentication Access Point.

Word 124 is the Authentication Access Port (AAP) lock word (ALW) and the four LSBs of this word are the lock bits. If these bits are 0xF, then AAP access is enabled. If the bits are not 0xF, AAP is disabled and it is impossible to access the device through the AAP. Bit 31 of the ALW may be used to allow AAP access under controlled conditions. If bit 31 is set to 1, software running on the device can unlock AAP access using the MSC_AAPUNLOCKCMD register. If bit 31 is cleared to 0, software will not be able to use MSC_AAPUNLOCKCMD to unlock AAP access. NOTE - locking the AAP completely (including the LSBs and bit 31) is irreversible. Once the AAP is locked, it will be impossible to perform an external mass erase and the AAP lock cannot be reset. The only way to program the device when the AAP is locked is through a bootloader or by SW already loaded into the FLASH.

Word 123 is Configuration Lock Word 1 (CLW1). Bit 0 is the Bank Switch Disable bit. Because the state of erased flash bits is 1, bank switching is disabled on dual-bank devices by default. To enable bank switching, this bit must be written to 0.

Word 122 is Configuration Lock Word 0 (CLW0). Bit 2 is the Pin Reset Soft bit. By default, a pin reset is handled as a soft reset (See 9.3.5 RESETn Pin Reset). Bit 1 is the bootloader enable bit. Because the state of erased flash bits is 1, the bootloader is enabled by default.

Note: A hard reset is required in order for changes to the lock bits to take effect. In typical use cases, this will be a power-on reset because pin reset is a soft reset by default (see above).

7.3.3 Device Information (DI) Page

This read-only page holds calibration data from the production test as well as a unique device ID. The page is further described in 4. Memory and Bus System.

7.3.4 Bootloader

The memory space includes an area for custom-programmed bootloaders. The available bootloader area is 38 kB for this device family. By default, the system is configured to boot directly into user software after system reset, and there is not a pre-programmed bootloader in the device. If a custom bootloader which follows Silicon Labs' bootloader recommendations outlined in *AN0003: UART Bootloader* (www.silabs.com/32bit-appnotes) is programmed into the bootloader area, or a Gecko Bootloader is programmed into the bootloader area, the system can be redirected to boot from this area by setting bit 1 in config lock word 0 (CLW0) at word 122 of the lockbit (LB) page. More information about Gecko Bootloader can be found in UG266: Silicon Labs Gecko Bootloader User's Guide for GSDK 3.2 and Lower and in UG489: Silicon Labs Gecko Bootloader User's Guide for GSDK 4.0 and Higher.

After any device reset, the bootloader area is accessible to both software reads and writes. Reading and writing of this area may be disabled with the MSC_BOOTLOADERCTRL register. Note that this register is write-once, so after writing the register, a reset of the system is required in order to change permissions again.

Note: Software should never erase "Reserved" pages when bootloader write/erase is enabled. Doing so may cause the device to become non-functional and irrevocably locked.

7.3.5 Post-Reset Behavior

Calibration values are automatically written to registers by the MSC before application code startup. The values are also available to read from the DI page for later reference by software. Other information such as the device ID and production date is also stored in the DI page and is readable from software.

If the bootloader is not bypassed, the system will boot up from the bootloader at address 0x0FE10000.

7.3.6 Flash Startup

On transitions from EM2/3 to EM0, the flash must be powered up. The time this takes depends on the current operating conditions. To have a deterministic startup-time, set STDLY0 in MSC_STARTUP to 0x64 and clear STDLY1, ASTWAIT, STWSEN and STWS. This will result in a 10 us delay before the flash is ready. The system will wake up before this, but the Cortex will stall on the first access to the flash until it is ready. Execute code from RAM or cache to get a quicker startup.

To get the fastest possible startup when waking, i.e. a startup that depends on the current operating conditions, set STDLY0 to 0x28 and set ASTWAIT in MSC_STARTUP. When configured this way, the system will poll the flash to determine when it is ready, and then start execution.

For even quicker startup, run code in beginning with a set of wait-states. Set STDLY0 to 0x32, STDLY1 to 0x32, and set ASTWAIT and STWSEN. Then configure STWS in MSC_STARTUP to the number of waitstates to run with. With this setup, sampling will begin with the given number of waitstates after 5 us, and the system will run with this number of waitstates for the remaining 5 us before returning to normal operation

A recommended setting for MSC_STARTUP register is to leave STDLY0 at its reset value and set ASTWAIT to one for active sampling Set STWSEN to zero to bypass the second delay period.

Flash wakeup on demand is supported when wakeup from EM2/3 to EM0. Set bit PWRUPONDEMAND of register MSC_CTRL to one to enable the power up on demand. When enabled during powerup, flash will enter sleep mode and waiting for either pending flash read transaction or software command to MSC_CMD.PWRUP bit. If software command wakeup, and interrupt of MSC_IF.PWRUPF will be flaged if the MSC_IEN.PWRUPF is set

7.3.7 Wait States

Table 7.3. Flash Wait States

Wait States	Frequency
WS0	no more than 25 MHz
WS1	above 25 MHz and no more than 40 MHz

7.3.7.1 One Wait-state Access

After reset, the HFCORECLK is normally 19 MHz from the HFRCO and the MODE field of the MSC_READCTRL register is set to WS1 (one wait-state). Software must not select a zero wait-state mode unless the clock is guaranteed to be 25 MHz or below, otherwise the resulting behavior is undefined. If a HFCORECLK frequency above 25 MHz is to be set by software, the MODE field of the MSC_READCTRL register must be set to WS1 or WS1SCBTP before the core clock is switched to the higher frequency clock source.

When changing to a lower frequency, the MODE field of the MSC_READCTRL register must be set to WS0 or WS0SCBTP only after the frequency transition has completed. If the HFRCO is used, wait until the oscillator is stable on the new frequency. Otherwise, the behavior is unpredictable.

7.3.7.2 Zero Wait State Access

At 25 MHz and below, read operations from flash may be performed without any wait-states. Zero wait-state access greatly improves code execution performance at frequencies from 25 MHz and below. By default, the Cortex-M4 uses speculative prefetching and If-Then block folding to maximize code execution performance at the cost of additional flash accesses and energy consumption.

7.3.8 Suppressed Conditional Branch Target Prefetch (SCBTP)

MSC offers a special instruction fetch mode which optimizes energy consumption by cancelling Cortex-M4 conditional branch target prefetches. Normally, the Cortex-M4 core prefetches both the next sequential instruction and the instruction at the branch target address when a conditional branch instruction reaches the pipeline decode stage. This prefetch scheme improves performance while one extra instruction is fetched from memory at each conditional branch, regardless of whether the branch is taken or not. To optimize for low energy, the MSC can be configured to cancel these speculative branch target prefetches. With this configuration, energy consumption is more optimal, as the branch target instruction fetch is delayed until the branch condition is evaluated.

The performance penalty with this mode enabled is source code dependent, but is normally less than 1% for core frequencies from 25 MHz and below. To enable the mode at frequencies from 25 MHz and below write WS0SCBTP to the MODE field of the MSC_READCTRL register. For frequencies above 25 MHz, use the WS1SCBTP mode, and for frequencies above 40 MHz, use the WS2SCBTP mode. An increased performance penalty per clock cycle must be expected compared to WS0SCBTP mode. The performance penalty in WS1SCBTP/WS2SCBTP mode depends greatly on the density and organization of conditional branch instructions in the code.

7.3.9 Cortex-M4 If-Then Block Folding

The Cortex-M4 offers a mechanism known as if-then block folding. This is a form of speculative prefetching where small if-then blocks are collapsed in the prefetch buffer if the condition evaluates to false. The instructions in the block then appear to execute in zero cycles. With this scheme, performance is optimized at the cost of higher energy consumption as the processor fetches more instructions from memory than it actually executes. To disable the mode, write a 1 to the DISFOLD bit in the NVIC Auxiliary Control Register; see the Cortex-M4 Technical Reference Manual for details. Normally, it is expected that this feature is most efficient at core frequencies above 25 MHz. Folding is enabled by default.

7.3.10 Instruction Cache

The MSC includes an instruction cache. The instruction cache for the internal flash memory is enabled by default, but can be disabled by setting IFCDIS in MSC_READCTRL. When enabled, the instruction cache typically reduces the number of flash reads significantly, thus saving energy. In most cases a cache hit-rate of more than 70 % is achievable. When a 32-bit instruction fetch hits in the cache the data is returned to the processor in one clock cycle. Thus, performance is also improved when wait-states are used (i.e. running at frequencies above 25 MHz).

The instruction cache is connected directly to the ICODE bus on the ARM core and functions as a memory access filter between the processor and the memory system, as illustrated in Figure 7.1 Instruction Cache on page 145. The cache consists of an access filter, lookup logic, SRAM, and two performance counters. The access filter checks that the address for the access is to on-chip flash memory (instructions in RAM are not cached). If the address matches, the cache lookup logic and SRAM is enabled. Otherwise, the cache is bypassed and the access is forwarded to the memory system. The cache is then updated when the memory access completes. The access filter also disables cache updates for interrupt context accesses if caching in interrupt context is disabled. The performance counters, when enabled, keep track of the number of cache hits and misses. The cachelines are filled up continuously one word at a time as the individual words are requested by the processor. Thus, not all words of a cacheline might be valid at a given time.

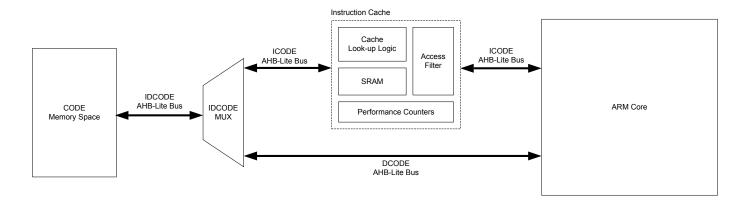

Figure 7.1. Instruction Cache

By default, the instruction cache is automatically invalidated when the contents of the flash is changed (i.e. written or erased). In many cases, however, the application only makes changes to data in the flash, not code. In this case, the automatic invalidate feature can be disabled by setting AIDIS in MSC_READCTRL. The cache can (independent of the AIDIS setting) be manually invalidated by writing 1 to INVCACHE in MSC_CMD.

Note: The instruction cache flush is not triggered at the event of a bus fault. As a result, when an instruction fetch results in a bus fault, invalid data may be cached. This means that the next time the instruction that caused the bus fault is fetched, the processor core will get the invalid cached data without any bus fault. In order to avoid invalid cached data propagation to the processor core, software should manually invalidate the instruction cache by writing 1 to INVCACHE in MSC_CMD at the event of a bus fault.

In general it is highly recommended to keep the cache enabled all the time. However, for some sections of code with very low cache hitrate more energy-efficient execution can be achieved by disabling the cache temporarily. To measure the hit-rate of a code-section, the built-in performance counters can be used. Before the section, start the performance counters by writing 1 to STARTPC in MSC_CMD. This starts the performance counters, counting from 0. At the end of the section, stop the performance counters by writing 1 to STOPPC in MSC_CMD. The number of cache hits and cache misses for that section can then be read from MSC_CACHEHITS and MSC_CACHEMISSES respectively. The total number of 32-bit instruction fetches will be MSC_CACHEHITS + MSC_CACHEMISSES. Thus, the cache hit-ratio can be calculated as MSC_CACHEHITS / (MSC_CACHEHITS + MSC_CACHEMISSES). When MSC_CACHEHITS overflows the CHOF interrupt flag is set. When MSC_CACHEMISSES overflows the CMOF interrupt flag is set. These flags must be cleared explicitly by software. The range of the performance counters can thus be extended by increasing a counter in the MSC interrupt routine. The performance counters only count when a cache lookup is performed. If the lookup fails, MSC_CACHEMISS-ES is increased. If the lookup is successful, MSC_CACHEHITS is increased. For example, a cache lookup is not performed if the cache is disabled or the code is executed from RAM.

Note: When caching of vector fetches and instructions in interrupt routines is disabled (ICCDIS in MSC_READCTRL is set), the performance counters do not count when these types of fetches occur (i.e. while in interrupt context).

By default, interrupt vector fetches and instructions in interrupt routines are also cached. Some applications may get better cache utilization by not caching instructions in interrupt context. This is done by setting ICCDIS in MSC_READCTRL. You should only set this bit based on the results from a cache hit ratio measurement. In general, it is recommended to keep the ICCDIS bit cleared. Note that look-ups in the cache are still performed, regardless of the ICCDIS setting - but instructions are not cached when cache misses occur inside

the interrupt routine. So, for example, if a cached function is called from the interrupt routine, the instructions for that function will be taken from the cache.

The cache content is not retained in EM2, EM3 and EM4. The cache is therefore invalidated regardless of the setting of AIDIS in MSC_READCTRL when entering these energy modes. Applications that switch frequently between EM0 and EM2/3 and executes the very same non-looping code almost every time will most likely benefit from putting this code in RAM. The interrupt vectors can also be put in RAM to reduce current consumption even further.

7.3.11 Low Voltage Flash Read

The devices support low voltage flash reads. Because it takes more time to read from flash with a lower voltage supply MSC_READCTRL.MODE should be programmed accordingly. It is recommended that software should follow certain sequences for supply voltage scaling up and down. See the EMU chapter for details.

Flash write/erase is not supported in low voltage mode. Any write/erase command will be ignored if flash is operated in a low voltage mode and the interrupt flag MSC IF.LVEWRITE will be set.

7.3.12 Bank Switching Operation

It is possible to swap the starting addresses of the two flash instances under software control by issuing a bank switch command. The BANKSWITCHED bit in the MSC_STATUS register indicates if address 0x0 currently points to flash instance 0 or flash instance 1. After power-on reset, flash instance 0 always starts at address 0x0. Writing a 1 to the SWITCHINGBANK bit in the MSC_CMD register swaps the two flash instances immediately.

The bank switch command must be executed from the bootloader region of flash or RAM, as doing so from one of the main flash instances can result in unpredictable behavior.

Note: Bank switching is disabled unless bit 0 of Configuration Lock Word 1 has been programmed to 0 prior to exit from power-on reset.

A typical use of bank switching is described here: During the chip power up sequence, the bootloader fetches parameters from fixed addresses of both flash instances. The parameters could be firmware revision numbers, error checking codes, or other flags. Based on these parameters, the bootloader determines whether or not bank switching is necessary. The bank switching operation must be executed before the CPU transfers execution control to the application in the selected flash instance.

7.3.13 Erase and Write Operations

Both page erase and write operations require that the address is written into the MSC_ADDRB register. For erase operations, the address may be any within the page to be erased. Load the address by writing 1 to the LADDRIM bit in the MSC_WRITECMD register. The LADDRIM bit only has to be written once when loading the first address. After each word is written the internal address register ADDR will be incremented automatically by 4. The INVADDR bit of the MSC_STATUS register is set if the loaded address is outside the flash and the LOCKED bit of the MSC_STATUS register is set if the page addressed is locked. Any attempts to command erase of or write to the page are ignored if INVADDR or the LOCKED bits of the MSC_STATUS register are set. To abort an ongoing erase, set the ERASEABORT bit in the MSC_WRITECMD register.

When a word is written to the MSC_WDATA register, the WDATAREADY bit of the MSC_STATUS register is cleared. When this status bit is set, software or DMA may write the next word.

A single word write is commanded by setting the WRITEONCE bit of the MSC_WRITECMD register. The operation is complete when the BUSY bit of the MSC_STATUS register is cleared and control of the flash is handed back to the AHB interface, allowing application code to resume execution.

For a DMA write the software must write the first word to the MSC_WDATA register and then set the WRITETRIG bit of the MSC_WRITECMD register. DMA triggers when the WDATAREADY bit of the MSC_STATUS register is set.

It is possible to write words twice between each erase by keeping at 1 the bits that are not to be changed. Let us take as an example writing two 16 bit values, 0xAAAA and 0x5555. To safely write them in the same flash word this method can be used:

- Write 0xFFFFAAAA (word in flash becomes 0xFFFFAAAA)
- Write 0x5555FFFF (word in flash becomes 0x5555AAAA)

Note:

- There is a maximum of two writes to the same word between each erase due to a physical limitation of the flash.
- Flash write/erase is not supported in low voltage mode. Any write/erase command will be ignored if flash is operated in a low voltage mode and the interrupt flag MSC_IF.LVEWRITE will be set.
- During a write or erase, flash read accesses not subject to read-while-write will be stalled, effectively halting code execution from flash. Code execution continues upon write/erase completion. Code residing in RAM may be executed during a write/erase operation regardless of whether read-while-write is enabled or not.

7.3.13.1 Read-While-Write

Parts with 512 kB or 1 MB of flash support read-while-write operation. For example, it is possible for the CPU to execute (read) code from the lower half of the flash while programming or erasing the upper half of the flash and vice versa. Enable read-while-write by setting the RWWEN bit in the MSC_WRITECTRL register.

The physical flash pages allocated to the lock bits, user data, and bootloader regions are interleaved between the two flash instances as shown below:

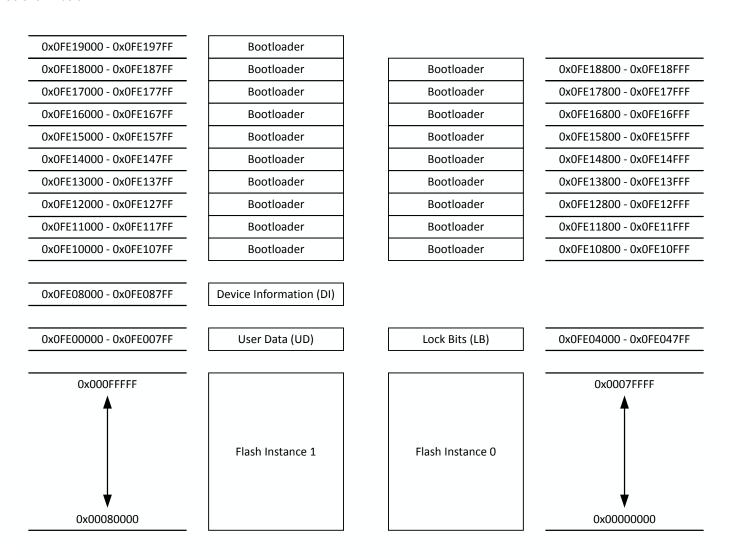

Figure 7.2. Flash Page Organization and Instance Association

The address ranges for flash instances 0 and 1 in Figure 7.2 Flash Page Organization and Instance Association on page 148 are for a 1 MB device. On a 512 kB device, flash instances 0 and 1 are half the size (256 kB vs. 512 kB) and are mapped starting at 0x0 and 0x40000, respectively, in order provide a contiguous address space. The arrangement of the lock bits, user data, and bootloader pages is the same in both cases.

7.3.13.2 Mass Erase

A mass erase can be initiated from software using ERASEMAIN0 and ERASEMAIN1 in MSC_WRITECMD. These commands will for devices supporting read-while-write start a masserase on the lower and upper half of the flash respectively. For devices not supporting read-while-write, MASSERASE0 will start a mass erase of the entire flash. Prior to initiating a mass erase, MSC_MASSLOCK must be unlocked by writing 0x631A to it. After a mass erase has been started, this register can be locked again to prevent runaway code from accidentally triggering a mass erase.

The regular flash page lock bits will not prevent a mass erase. To prevent software from initiating mass erases, use the mass erase lock bits in the mass erase lock word (MLW).

7.4 Register Map

The offset register address is relative to the registers base address.

Offset	Name	Туре	Description
0x000	MSC_CTRL	RWH	Memory System Control Register
0x004	MSC_READCTRL	RWH	Read Control Register

28	SCBTP	0	RW	Suppress Conditional Branch Target Perfetch

Enable suppressed Conditional Branch Target Prefetch (SCBTP) function. SCBTP saves energy by delaying Cortex-M conditional branch target prefetches until the conditional branch instruction is in the execute stage. When the instruction reaches this stage, the evaluation of the branch condition is completed and the core does not perform a speculative prefetch of both the branch target address and the next sequential address. With the SCBTP function enabled, one instruction fetch is saved for each branch not taken, with a negligible performance penalty.

27:26	Reserved	To ensure tions	compatibility	with future devices, always write bits to 0. More information in 1.2 Conven-
25.24	MODE	0x1	RWH	Read Mode

After reset, the core clock is 19 MHz from the HFRCO and the MODE field of MSC_READCTRL register is set to WS1. The reset value is WS1 because the HFRCO may produce a frequency above 19 MHz before it is calibrated. A large wait states is associated with high frequency. When changing to a higher frequency, this register must be set to a large wait states first before the core clock is switched to the higher frequency. When changing to a lower frequency, this register should be set to lower wait states after the frequency transition has been completed. If the HFRCO is used as clock source, wait until the oscillator is stable on the new frequency to avoid unpredictable behavior. See Flash Wait-States table for the corresponding threshold for different wait-states.

	Value	Mode		Description
	0	WS0		Zero wait-states inserted in fetch or read transfers
	1	WS1		One wait-state inserted for each fetch or read transfer. See Flash Wait-States table for details
	2	WS2		Two wait-states inserted for eatch fetch or read transfer. See Flash Wait-States table for details
	3	WS3		Three wait-states inserted for eatch fetch or read transfer. See Flash Wait-States table for details

8. LDMA - Linked DMA Controller

Quick Facts

What?

The LDMA controller can move data without CPU intervention, effectively reducing the energy consumption for a data transfer.

Why?

The LDMA can perform data transfers more energy efficiently than the CPU and allows autonomous operation in low energy modes. For example the LEUART can provide full UART communication in EM2 Deep Sleep, consuming only a few μA by using the LDMA to move data between the LEUART and RAM.

How?

The LDMA controller has multiple highly configurable, prioritized DMA channels. A linked list of flexible descriptors makes it possible to tailor the controller to the specific needs of an application.

8.1 Introduction

The Linked Direct Memory Access (LDMA) controller performs memory transfer operations independently of the CPU. This has the benefit of reducing the energy consumption and the workload of the CPU, and enables the system to stay in low energy modes while still routing data to memory and peripherals. For example, moving data from the LEUART to memory or memory to LEUART. Each of the DMA channels on the EFR32 can be connected to any of the EFR32 peripherals.

8.1.1 Features

- · Flexible Source and Destination transfers
 - · Memory-to-memory
 - · Memory-to-peripheral
 - · Peripheral-to-memory
 - · Peripheral-to-peripheral
- DMA transfers triggered by peripherals, software, or linked list
- · Single or multiple data transfers for each peripheral or software request
- · Inter-channel and hardware event synchronization via trigger and wait functions
- · Supports single or multiple descriptors
 - · Single descriptor
 - · Linked list of descriptors
 - · Circular and ping-pong buffers
 - · Scatter-Gather
 - · Looping
 - · Pause and restart triggered by other channels
 - · Sophisticated flow control which can function without CPU interaction
- · Channel arbitration includes:
 - · Fixed priority
 - · Simple round robin
 - · Round robin with programmable multiple interleaved entries for higher priority requesters
- · Programmable data size and source and destination address strides
- · Programmable interrupt generation at the end of each DMA descriptor execution
- · Little-endian/big-endian conversion
- · DMA write-immediate function

8.2 Block Diagram

An overview of the LDMA and the modules it interacts with is shown in Figure 8.1 LDMA Block Diagram on page 172.

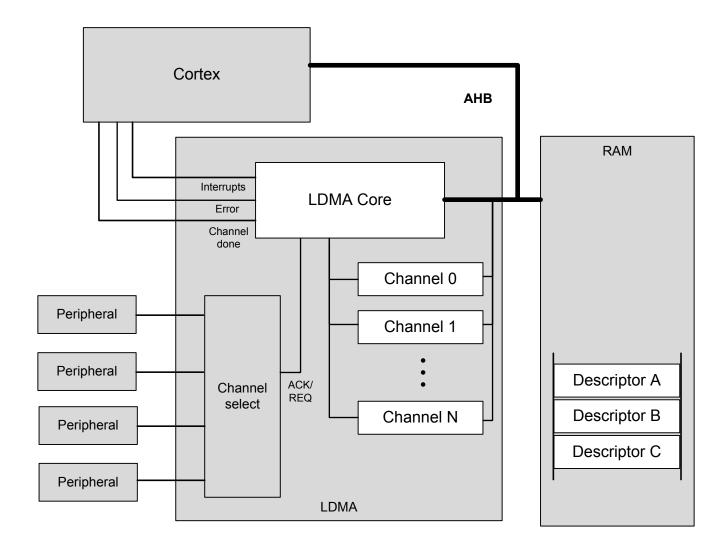

Figure 8.1. LDMA Block Diagram

The Linked DMA Controller consists of three main parts

- · A DMA core that executes transfers and communicates status to the core
- · A channel select block that routes peripheral DMA requests and acknowledge signals to the DMA
- · A set of internal channel configuration registers for tracking the progress of each DMA channel

The DMA has access to all system memory through the AHB bus and the AHB->APB bridge. It can load channel descriptors from memory with no CPU intervention.

8.3 Functional Description

The Linked DMA Controller is highly flexible. It is capable of transferring data between peripherals and memory without involvement from the processor core. This can be used to increase system performance by off-loading the processor from copying large amounts of data or avoiding frequent interrupts to service peripherals needing more data or having available data. It can also be used to reduce the system energy consumption by making the LDMA work autonomously with some EM2/3 peripherals for data transfer without having to wake up the processor core from sleep.

The Linked DMA Controller has 8 independent channels. Each of these channels can be connected to any of the available peripheral DMA transfer request input sources by writing to the channel configuration registers, see 8.3.2 Channel Configuration. In addition, each channel can also be triggered directly by software, which is useful for memory-to-memory transfers.

The channel descriptors determine what the Linked DMA Controller will do when it receives DMA transfer request. The initial descriptor is written directly to the LDMA's channel registers. If desired, the initial descriptor can link to additional linked descriptors stored in memory (RAM or Flash). Alternatively, software may also load the initial descriptor by writing the descriptor address to the LDMA_CHx_LINK register and then setting the corresponding bit the LDMA_LINKLOAD register.

Before enabling a channel, the software must take care to properly configure the channel registers including the link address and any linked descriptors. When a channel is triggered, the Linked DMA Controller will perform the memory transfers as specified by the descriptors. A descriptor contains the memory address to read from, the memory address to write to, link address of the next descriptor, the number of bytes to be transferred, etc. The channel descriptor is described in detail in 8.3.7 Channel Descriptor Data Structure.

The Linked DMA Controller supports both fixed priority and round robin arbitration. The number of fixed and round robin channels is programmable. For round robin channels, the number of arbitration slots requested for each channel is programmable. Using this scheme, it is possible to ensure that timing-critical transfers are serviced on time.

DMA transfers take place by reading a block of data at a time from the source, storing it in the LDMA's local FIFO, then writing the block out to the destination from the FIFO. Interrupts may optionally be signaled to the CPU's interrupt controller at the end of any DMA transfer or at the completion of a descriptor if the DONEIFSEN bit is set. An AHB error will always generate an interrupt.

8.3.1 Channel Descriptor

Each DMA channel has descriptor registers. A transfer can be initialized by software writing to the registers or by the DMA itself copying a descriptor from RAM to memory. When using a linked list of descriptors the first descriptor should be initialized by the CPU. The DMA itself will then copy linked descriptors to its descriptor registers as required. In addition to manually initializing the first transfer, software may also cause the LDMA to load the initial descriptor by writing the descriptor address to the LDMA_CHx_LINK register and then setting the corresponding bit the LDMA_LINKLOAD register.

The contents of the descriptor registers are dynamically updated during the DMA transfer. The contents of descriptors in memory are not edited by the controller.

Some descriptor field values are only used for linked descriptors. For example, the SRCMODE and DSTMODE bits of the LDMA_CHx_CTRL registers determine if a linked descriptor is using relative or absolute addressing. Software writes to the address registers will always use absolute addressing and never set these bits. Therefore, these bits are read only.

8.3.1.1 DMA Transfer Size

A DMA transfer is the smallest unit of data that can be transfered by the LDMA. The LDMA supports byte, half-word and word sized transfers. The SIZE field in the LDMA_CHx_CTRL register specifies the data width of one DMA transfer.

8.3.1.2 Source/Destination Increments

The SRCINC and DSTINC in the LDMA_CHx_CTRL register determines the increment between DMA transfers. The increment is in units of DMA transfers and using an increment size of 1 will transfer contiguous bytes, half-words, or words depending on the value of the SIZE field. Multiple unit increments are useful for transferring or packing/unpacking alligned data. For example using an increment of 4 with a size of BYTE will transfer word aligned bytes. An increment of 2 units with a size of HALFWORD is suitable for the transfer of word aligned half-word data. The LDMA can also pack or unpack data by using a different increment size for source and destination. For example - to convert from word aligned byte data (unpacked) to contiguous byte data (packed), set the SIZE to BYTE, SRCINC to 4, and DSTINC to 1.

SRCINC or DSTINC may also be set to NONE which will cause the LDMA to read or write the same location for every DMA transfer. This is useful for accessing peripheral FIFO or data registers.

8.3.1.3 Block Size

The block size defines the amount of data transferred in one arbitration. It consists of one or more DMA transfers. See 8.3.6.1 Arbitration Priority for more details.

8.3.1.4 Transfer Count

The descriptor transfer count defines how many DMA transfers to perform. The number of bytes transferred by the descripter will depend on both the transfer count XFERCNT and the SIZE field settings. TOTAL_BYTES = XFERCNT * SIZE

8.3.1.5 Descriptor List

A descriptor list consists of one or more descriptors which are executed in serially. This list may be a simple sequence of descriptors, a loop of descriptors, or a combination of the two.

Each descriptor in the list can be one of several types.

- Single Transfer descriptor: Transfers TOTAL_BYTES of data and then stops.
- · Linked Transfer descriptor: Transfers TOTAL_BYTES of data and then loads the next linked descriptor.
- Loop Transfer descriptor: Transfers TOTAL BYTES of data and performs loop control (see 8.3.2.2 Loop Counter).
- Sync descriptor: Handle synchronization of the list with other entities (see 8.3.7.2 SYNC Descriptor Structure).
- WRI descriptor: Writes a value to a location in memory (see 8.3.7.3 WRI Descriptor Structure).

8.3.1.6 Addresses

Before initiating a transfer, software should write the source address, destination address, and if applicable the link address to the descriptor registers. Alternatively, software may load a descriptor from memory by writing the descriptor address to the LDMA_CHx_LINK register and setting the corresponding bit in the LDMA_LINKLOAD register.

During a DMA transfer, the DMA source and destination address registers are pointers to the next transfer address. The LDMA will update the SRC and DST addresses after each transfer. If software halts a DMA transfer by clearing the enable bit, the SRC and DST addresses will indicate the next transfer address.

When a desriptor is finished the DMA will either halt or load the next (linked) descriptor depending on the value of the LINK field in the LDMA_Chx_LINK register. After loading a linked descriptor, the descriptor registers will reflect the content of the loaded descriptor. Note that the linked descriptor must be word aligned in memory. The two least significant bits of the LDMA_CHx_LINK register are used by the LINK and LINKMODE bits. The two least significant bits of the link address are always zero.

8.3.1.7 Addressing Modes

The DMA descriptors support absolute addressing or relative addressing. When using relative addressing, the offset is relative to the current contents of the respective address registers. Regardless of the descriptor addressing modes, the address registers always indicate the absolute address. For example, when loading a descriptor using relative SRC addressing, the LDMA will add the descriptor source address (offset) to the contents of the SRCADDR register (base address). After loading, the SRCADDR register will indicate the absolute address of the loaded descriptor.

The initial descriptor must use absolute addressing. The LDMA will ignore the DSTMODE, SRCMODE, and LINKMODE bits for the initial descriptor and interpret the addresses as an absolute addresses.

Relative addressing is most useful for the link address. The initial descriptor will indicate the absolute address of the linked descriptors in memory. The linked descriptors might be an array of structures. In this case the offset between descriptors is constant and is always 4 words or 16 bytes (each descriptor has 4 words). The LINK address is not incremented or decremented after each transfer. Thus, a relative offset of 0x10 may be used for all linked descriptors.

The source and destination addresses also support relative addressing. When using relative addressing with the source or destination address registers, the LDMA adds the relative offset to the current contents of the respective address register. Since the source and destination addresses are normally incremented after each transfer, the final address will point to one unit past the last transfer. Thus, an offset of zero will give the next sequential data address.

See the example 8.4.6 2D Copy for an common use of relative addressing.

8.3.1.8 Byte Swap

Enabling byte swap reverses the endianness of the incoming source data read into the LDMA's FIFO. Byte swap is only valid for transfer sizes of word and half-word. Note that linked structure reads are not byte swapped.

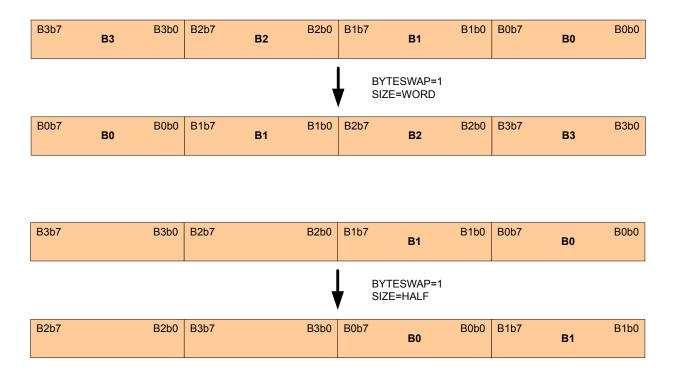

Figure 8.2. Word and Half-Word Endian Byte Swap Examples

8.3.1.9 DMA Size and Source/Destination Increment Programming

The DMA channels' SIZE, SRCINC, and DSTINC bit-fields are programmed to best utilize memory resources. They provide a means for memory packing and unpacking, as well as for matching the size of data being transmitted to or received from an IO peripheral. The following figure shows how 32-bit words of data are read from a memory source into the DMA's internal transfer FIFO, and then written out to the memory destination. The memory organization in bytes is shown as well as the first read to and write from the DMA's FIFO.

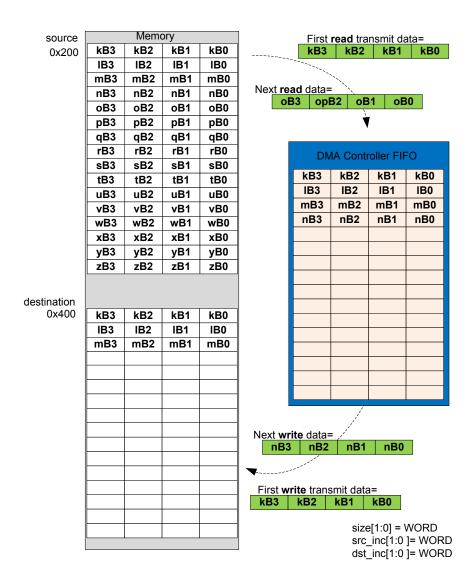

Figure 8.3. Memory-to-Memory Transfer WORD Size Example

The next example shows four variations of half-word sized transfers, with all possible combinations of half- and full-word source and destination increments. Note that when the size and source/destination increments are all configured for half-word, the resulting DMA transfer organization is equivalent to the full-word sized transfer in the previous example. The difference is that the half-word configuration requires twice as many DMA transfers.

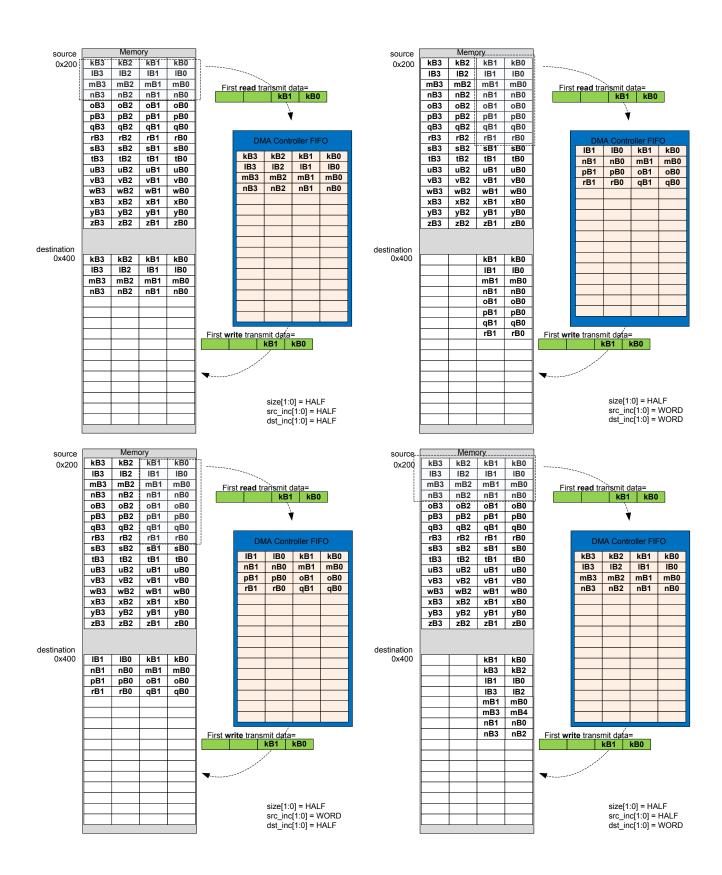

Figure 8.4. Memory-to-Memory Transfer HALF Size Examples

Fields SRCINCSIGN and DSTINCSIGN allow for address decrement. These can be used to mirror an image, for example, in the pixel copy application.

8.3.2 Channel Configuration

Each DMA channel has associated configuration and loop counter registers for controlling direction of address increment, arbitration slots, and descriptor looping.

8.3.2.1 Address Increment/Decrement

Normally DMA transfers increment the source and destination addresses after each DMA transfer. Each channel is also capable of decrementing the source and/or destination addresses after each DMA transfer. This may be useful for flipping an array or copying data from tail to head. For example, a data packet might be prepared as an array of data with increasing addresses and then transmitted from the highest address to the lowest address, from tail to head.

After reset the SRCINCSIGN and DSTINCSIGN bits in the LDMA_CHx_CFG register are cleared causing the source and destination addresses to increment after each transfer. If the SRCINCSIGN bit is set , the DMA will decrement the source address after each transfer. If the DSTINCSIGN bit in the LDMA_CHx_CFG register is set , the DMA will decrement the destination address after each transfer. Setting only one of these bits will flip the data. Setting both bits will copy from tail to head, but will not flip the data.

The SRCINCSIGN and DSTINCSIGN bits apply to all descriptors used by that channel. Software should take care to set the starting source and/or destination address to the highest data address when decrementing.

8.3.2.2 Loop Counter

Each channel has a LDMA_CHx_LOOP register that includes a loop counter field. To use looping, software should initialize the loop counter with the desired number of repetitions before enabling the transfer. A descriptor with the DECLOOPCNT bit set to TRUE will repeat the loop and decrement the loop counter until LOOPCNT = 0.

For a looping descriptor, with DECLOOPCNT=1, the LINK address in the LDMA_CHx_LINK register is used as the loop address. While LOOPCNT is greater than zero, the descriptor will execute and then the LDMA will load the next descriptor using the address specified in the LDMA_CHx_LINK register. This feature enables looping of multiple descriptors. To repeat a single descriptor, the LINK address of the descriptor should point to itself.

After LOOPCNT reaches zero, if the LINK bit in the descriptor LINK word is clear the transfer stops. If the LINK bit is set, the LDMA will load the next sequential descriptor located immediately following the looping descriptor. The behavior of the LINK bit is different for a looping descriptor. This is necessary because the LINK address is re-purposed as the loop address for a looping descriptor.

Note that LOOPCNT sets the number of repeats, not the number of iterations. The total number of loop iterations will be LOOPCNT plus 1. Normally, the LOOPCNT should be set to one or more repeats.

Also note that because there is only one LOOPCNT per channel, software intervention is required to update the LOOPCNT if a sequence of transfers contains multiple loops. It is also possible to use a write immediate DMA data transfer to update the LDMA CHx LOOP register.

8.3.3 Channel Select Configuration

The channel select block determines which peripheral request signal connects to each DMA channel.

This configuration is done by software through the SOURCESEL and SIGSEL fields of the LDMA_CHn_REQSEL register. SOURCE-SEL selects the peripheral and SIGSEL picks which DMA request signals to use from the selected peripheral.

8.3.4 Starting a Transfer

A transfer may be started by software, a peripheral request, or a descriptor load.

Software may initiate a transfer by setting the bit for the desired channel in the LDMA_SREQ register. In this case the channel should set SOURCESEL to NONE to prevent unintentional triggering of the channel by a peripheral.

A peripheral may trigger the channel by configuring the peripheral source and signal as described in 8.3.3 Channel Select Configuration

The LDMA may also be configured to begin a transfer immediately after a new descriptor is loaded by setting the STRUCTREQ field of the LDMA CHx CTRL register or descriptor word.

This configuration is done by software through the SOURCESEL and SIGSEL fields of the LDMA_CHn_REQSEL register. SOURCE-SEL selects the peripheral and SIGSEL picks which DMA request signals to use from the selected peripheral.

8.3.4.1 Peripheral Transfer Requests

By default peripherals issue a Single Request (SREQ) when any data is present. For peripherals with a data buffer or FIFO this occurs any time the FIFO is not empty. Upon receiving an SREQ the LDMA will perform one DMA transfer and stop till another request is made.

It is generally more efficient to wait for a peripheral to accumulate data and transfer in a burst. This both reduces overhead of the DMA engine and allows EM2 peripherals to save power by using the LDMA less often. To enable this set the IGNORESREQ bit in the LDMA_CHx_CTRL register (or descriptor) which will cause the LDMA to ignore SREQ's and wait for a full Request (REQ) signal. When the REQ is received the entire descriptor will be executed. For most peripherals with a FIFO the REQ signal is set when the FIFO is full, or a predetermined threshold has been reached. See the individual peripheral chapters for more information.

8.3.5 Managing Transfer Errors

LDMA transfer errors are normally managed using interrupts. Software should clear the ERROR flag in the bit in the LDMA_IF register and enable error interrupts by setting the ERROR bit in the LDMA_IEN register before initiating a DMA transfer.

The LDMA interrupt handler should check the ERROR flag bit in the LDMA_IF register. If the ERROR flag bit is set, it should then read the CHERROR field in the LDMA_STATUS register to determine the errant channel. The interrupt handler should reset the channel and clear the ERROR flag bit in the LDMA_IF register before returning.

8.3.6 Arbitration

While multiple channels are configured simultaneously the LDMA engine can only be actively copying data for one channel at a time. Arbitration determines which channel is being serviced at any point in time. The LDMA will choose a channel through arbitration, transfer BLOCK_SIZE elements of that channel and then arbitrate again choosing another channel to service. This allows high priority channels to be serviced while lower priority channels are in the middle of a transfer.

8.3.6.1 Arbitration Priority

There are two modes in determining priority when the controller arbitrates: fixed priority and round robin priority.

In fixed priority mode, channel 0 has the highest priority. As the channel number increases, the priority decreases. When the LDMA controller is idle or when a transfer completes, the highest priority channel with an active request is granted the transfer. This mode guarantees smallest latency for the highest priority requesters. It is best suited for systems where peak bandwidth is well below LDMA controller's maximum ability to serve. The drawback of this mode is the possibility of starvation for lowest priority requesters.

In the round robin priority mode, each active requesting channel is serviced in the order of priority. A late arriving request on a higher priority channel will not get serviced until the next round. This mode minimizes the risk of starving low-priority latency-tolerant requesters. The drawback of this mode is higher risk of starving low-latency requesters.

The NUMFIXED field in the LDMA_CTRL register determines which channels are fixed priority and which are round robin. Channels lower than NUMFIXED are fixed priority while those above it are round robin. A value of 0x0 implies all channels are round robin. A value of 0x4 implies channels 0 through 3 are fixed priority and 4 through 7 are round robin. A value of 7 implies that channels 0 through 6 are fixed and channel 7 is round robin. This is functionally equivalent to having 8 fixed priority channels.

Fixed priority channels always take priority over round robin. As long as NUMFIXED is greater than 0, there is a possibility that a higher priority channel can starve the remaining channels.

To address the drawbacks of using fixed priority or round robin priority the LDMA implements the concept of arbitration slots. This allows for channels to have high bandwidth and low latency while preventing starvation of latency tolerant low priority channels.

Each channel has a two bit ARBSLOT field in its LDM_CHx_CFG register. This field only applies to channels marked as round robin (determined by NUMFIXED). The channels in the same arbitration slot are treated equally with round robin scheduling. Channels marked with a higher arbitration slot will get serviced more frequently. By default all channels are placed in arbitration slot 1.

Every time the channels in slot 1 get serviced the channels in slot 2 get serviced twice, those in slot 4 get serviced 4 times, and those in slot 8 get serviced 7 times. The specific arbitration allocation can be seen by the following table. The highest arbitration slot is serviced every other arbitration cycle, allowing for low latency response. If there are no requests from channels in arbitration slot then that slot is immediately skipped.

Table 8.1. Arbitration Slot Order

Arbslot order	8	4	8	2	8	4	8	1	8	4	8	2	8	4
Arbslot1								1						
Arbslot2				1								1		
Arbslot4		1				1				1				1
Arbslot8	1		1		1		1		1		1		1	

The top row shows the order at which the arbitration slots are executed. The remaining part of the table shows a more visual interpretation of the arbitration order.

For example, if we have one low latency channel (CHNL0) and two latency tolerant channels (CHNL1 and CHNL2). We could use the following settings.

LDMA CTRL.NUMFIXED = 0; set round robin for all channels.

CHNL0_CFG.ARBSLOTS = TWO;

CHNL1 CFG.ARBSLOTS = ONE;

CHNL2_CFG.ARBSLOTS = ONE;

If all channels are constantly requesting transfers, then the arbitration order is: CHNL0, CHNL1, CHNL0, CHNL1, CHNL0, CHNL1, CHNL0, CHNL2, CHNL0, etc

Note, there are no channels assigned to arbitration slot four or eight in this example, so those slots are skipped and the final sequence is ARBSLOT2, ARBSLOT1, ARBSLOT2, ARBSLOT1, etc...

Channel 1 and Channel 2 are selected in round robin order when arbitration slot 1 is executed.

If we replace the ARBSLOTS value for channel 0 with EIGHT, then the sequence would look like the following:

CHNL0, CHNL0, CHNL0, CHNL1, CHNL1, CHNL0, CHNL0, CHNL2, CHNL0, CHNL0, CHNL0, CHNL0, CHNL1, etc.

8.3.6.2 DMA Transfer Arbitration

In addition to the inter channel arbitration, software can configure when the controller arbitrates during a DMA transfer. This provides reduced latency to higher priority channels when configuring low priority transfers with more arbitration cycles.

The LDMA provides four bits that configure how many DMA transfers occur before it re-arbitrates. These bits are known as the BLOCK-SIZE bits and they map to the arbitration rate as shown below. For example, if BLOCKSIZE = 4 then the arbitration rate is 6, that is, the controller arbitrates every 6 DMA transfers.

Table 8.2 AHB Bus Transfer Arbitration Interval on page 181 lists the arbitration rates.

Table 8.2. AHB Bus Transfer Arbitration Interval

BLOCKSIZE	Arbitrate After x DMA transfers
0	x = 1
1	x = 2
2	x = 3
3	x = 4
4	x = 6
5	x = 8
6	x = 12
7	x = 16
8	x = 24
9	x = 32
10	x = 64
11	x = 128
12	x = 256
13	x = 512
14	x = 1024
15	x = lock

Note: Software must take care not to assign a low-priority channel with a large BLOCKSIZE because this prevents the controller from servicing high-priority requests, until it re-arbitrates.

The number of DMA transfers that need to be done is specified by the user in XFERCNT. When XFERCNT > BLOCKSIZE and is not an integer multiple of BLOCKSIZE then the controller always performs sequences of BLOCKSIZE transfers until XFERCNT < BLOCKSIZE remain to be transferred. The controller performs the remaining XFERCNT transfers at the end of the DMA cycle.

Software must store the value of the BLOCKSIZE bits in the channel control data structure. See 8.3.7.1 XFER Descriptor Structure for more information about the location of the BLOCKSIZE bits in the data structure.

8.3.7 Channel Descriptor Data Structure

Each channel descriptor consists of four 32-bit words:

- · CTRL control word contains information like transfer count and block size.
- SRC source address points to where to copy data from
- · DST destination address points to where to copy data to
- · LINK link address points to where to load the next linked descriptor

These words map directly to the LDMA_CHx_CTRL, LDMA_CHx_SRC, LDMA_CHx_DST, and LDMA_CHx_LINK registers. The usage of the SRC and DST fields may differ depending on the structure type

There are three different types of descriptor data structures: XFER, SYNC, and WRI

8.3.7.1 XFER Descriptor Structure

This descriptor defines a typical data transfer which may be a Normal, Link, or Loop transfer.

Only this structure type can be written directly into LDMA's registers by the CPU. All descriptors may be linked to. Refer to the register descriptions for additional information.

For specifying XFER structure type, set STRUCTTYPE to 0. See the peripheral register descriptions for information on the fields in this structure.

SRC															S	RCA	ADD	R														
DST															D	STA	ADD	R														
LINK														L	INKA	ADD	R														LINK	LINKMODE

8.3.7.2 SYNC Descriptor Structure

This descriptor defines an intra-channel synchronizing structure. It allows the channel to wait for some external stimulus before continuing on to the next descriptor. This structure is also used to provide stimulus to another channel to indicate that it may continue.

For example channel 1 may be configured to transfer a header into a buffer while channel 2 is simultaneously transferring data into the same structure. When channel 1 has completed it can wait for a sync signal from channel 2 before transferring the now complete buffer to a peripheral.

Synch descriptors do nothing until a condition is met. The condition is formed by the SYNCTRIG field in the LDMA_SYNC register and the MATCHEN and MATCHVAL fields of the descriptor. When (SYNCTRIG & MATCHEN) == (MATCHVAL & MATCHEN) the next descriptor is loaded. In addition to waiting for the condition a Link descriptor can set or clear bits in SYNCTRIG to meet the conditions of another channel and cause it to continue. The CPU also has the ability to set and clear the SYNCTRIG bits from software.

This structure type can only be linked in from memory.

For specifying SYNC structure type, set STRUCTTYPE to 1.

Bit Name Description

This bit-field serves as the SYNCTRIG match value. A sync match triggers the load of the next linked DMA structure as specified by link_mode, when: (SYNCTRIG & MATCHEN) == (MATCHVAL & MATCHEN).

8.3.7.3 WRI Descriptor Structure

This descriptor defines a write-immediate structure. This allows a list of descriptors to write a value to a register or memory location. For example, if a channel wishes to perform two loops in a descriptor sequence a WRI may be used to program the loop count for the second loop.

This structure type can only be linked in from memory.

For specifying WRI structure type, set STRUCTTYPE to 2.

Name															В	it Po	sitio	on														
	31	30	29	28	27	26	25	24	23	22	21	20	19	8	17	16	15	4	13	12	7	10	6	œ	7	9	2	4	3	2	_	0

Bit	Name	Description
1:0	STRUCTTYPE	Descriptor Type
	This field indicates which	ch type of descriptor this is. It must be 2 for a WRI descriptor.
20	DONEIFSEN	Done if Set indicator
	If set the interrupt flag v	vill be set when descriptor completes.
31:0	IMMVAL	Immediate Value for Write
	This bit-field specifies the write occurs for WRI str	he immediate data value that is to be written to the address pointed to by DSTADDR. Only one ructures.
31:0	DSTADDR	Address to write
	This bit-field specifies the	he address the immediate data should be written to.

8.3.8 Interaction With the EMU

The LDMA interacts with the Energy Management Unit (EMU) to allow transfers from a low energy peripheral while in EM2 Deep Sleep. For example, when using the LEUART in EM2 Deep Sleep the EMU can wake up the LDMA sufficiently long to allow data transfers to occur. See section "DMA Support" in the LEUART documentation.

Similarly, when using the ADC in EM2 Deep Sleep or EM3 Stop the EMU can wake up the LDMA as needed to allow data transfers to occur.

Table 8.3 List of Peripherals Capable of Waking Up LDMA in EM2 Deep Sleep or EM3 Stop on page 185 shows complete list of peripherals that are capable of waking up LDMA via EMU in EM2 Deep Sleep or EM3 Stop

Table 8.3. List of Peripherals Capable of Waking Up LDMA in EM2 Deep Sleep or EM3 Stop

Peripheral

CSEN
DAC0
ESENSE
EUARTO

8.3.9 Interrupts

The LDMA_IF Interrupt flag register contains one DONE bit for each channel and one combined ERROR bit. When enabled, these interrupts are available as interrupts to the Cortex-M4 core. They are combined into one interrupt vector, DMA_INT. If the interrupt for the DMA is enabled in the ARM Cortex-M4 core, an interrupt will be made if one or more of the interrupt flags in LDMA_IF and their corresponding bits in LDMA_IEN are set.

When a descriptor finishes execution the interrupt flag for that channel will be set if the DONEIFSEN field of the LDMA_CHx_LOOP register is set. If LINK and DONEIFSEN are both set when the descriptor completes the interrupt and the linked descriptor will be immediatly loaded. When the final descriptor in a linked list (LINK = 0) is finished the interrupt flag is always set regardless of the state of DONEIFSEN.

8.3.10 Debugging

For a peripheral request DMA transfer, if software sets a bit for a channel in the LDMA_DBGHALT register then the DMA will halt durring a debug halt and the SRC and DST registers in the debug window will show the transfer in progress. Otherwise, during debug halt the DMA will continue to run and complete the entire transfer causing the descriptor registers to indicate the transfer has completed.

8.4 Examples

This section provides examples of common LDMA usage. All examples assume the LDMA is in the reset state with the channel being configured disabled and LDAM_CHx_CFG, LDMA_CHx_LOOP, and LDMA_CHx_LINK cleared.

8.4.1 Single Direct Register DMA Transfer

This simple example uses only the Channel Descriptor registers directly and does not use linking. Software writes directly to the LDMA channel registers. This example does not use a memory based descriptor list.

This example is suitable for most simple transfers that are limited to transferring one block of data. It supports anything that can be done using a single descriptor. This includes endian conversion and packing/unpacking data. Channel 0 is used for this example.

The LDMA will be used to copy 127 contiguous half words (254 bytes) from 0x0 to 0x1000. It will allow arbitration every 4 transfers and is triggered by a CPU write to the LDMA_SWREQ register. The CH0 interrupt flag will be set when the transfer completes since the descriptor does not link to another descriptor.

- Configure LDMA_CH0_CTRL
 - DSTMODE = 0 (absolute)
 - SRCMODE = 0 (absolute)
 - SIZE = HALFWORD (16 bits)
 - DSTINC = 0 (1 half-word)
 - SRCINC = 0 (1 half-word)
 - DECLOOPCNT=0 (unused)
 - REQMODE = 1 (one request transfers all data)
 - BLOCKSIZE = 3 (4 transfers)
 - BYTESWAP=0 (no byte swap)
 - XFERCNT=127 (transfer 127 half words)
 - STRUCTTPYE=0 (TRANSFER)
- · Write source address to LDMA CH0 SRC register
- Write destination address to LDMA CH0 DST register
- · Configure the LDMA_CH0REQSEL register for the desired peripheral or select none for a memory-to-memory transfer
- · Clear and enable interrupts.
 - Write a 1 to bit 0 of the LDMA IFC register to clear the CH0 DONE flag
 - Write a 1 to bit 0 of the LDMA IEN register to enable the CH0 interrupt
- · Write a 1 to bit 0 of the LDMA_CHEN register to enable CH0

The REQMODE field is normally cleared to zero for a peripheral request transfer and will transfer the specified block size for each peripheral request. The REQMODE may be set to 1 for a memory-to-memory transfer or any time it is desired for a single DMA request to initiate complete transfer.

8.4.2 Descriptor Linked List

This example shows how to use a Linked List of descriptors. Each descriptor has a link address which points to the next descriptor in the list. A descriptor may be removed from the Linked list by altering the Link address of the one before it to point to the one after it. Descriptor Linked lists are useful when handling an array of buffers for communication data. For example, a bad packet can be removed from a receiver queue by simply removing the descriptor from the linked list.

Software loads the first descriptor into the DMA by writing the descriptor address to LDMA_CHx_LINK and setting the bit for that channel in the LDMA_LINKLOAD register. This method is preferred when using a linked list in memory since it treats the first descriptor just like all the others. However, it is also allowed for software to write the first descriptor directly to the LDMA registers.

In this example 4 descriptors are executed in series, the interrupt flag is set after the 2nd and 4th (last) descriptors have completed.

- · Prepare a list of descriptors using the XFER structure type in RAM
- · Initialize the CTRL, SRC, and DST members as desired
 - · Setting STRUCTREQ in the CTRL word for descritpors 2-4 will cause them to begin transfering data as soon as they are loaded.
- Write 0x00000013 to the LINK member of all but the last descriptor
 - LINKMODE = 1 (relative addressing)
 - LINK = 1 (Link to the next descriptor)
 - LINKADDR = 0x00000010 (size of descriptor)
- · Set the DONEIFSEN bit in the CTRL member of the 2nd structure so that the interrupt flag will be set when it completes
- Write 0x00000000 to the LINK member of the last descriptor
 - LINK = 0 (Do not link to the next descriptor)
 - LINKMODE = 0 (don't care)
 - LINKADDR = 0x00000000 (don't care)

Each descriptor now points to the start of the next descriptor as shown on the left in Figure 8.5 Descriptor Linked List on page 187. To remove a descriptor from the linked list modify the LINK address of the descriptor of the one before to point to the one after. For example to remove the third descriptor, add 0x00000010 to the LINK register of the second descriptor. The second descriptor will now point to the forth descriptor and skip over the third descriptor as shown on the right in Figure 8.5 Descriptor Linked List on page 187.

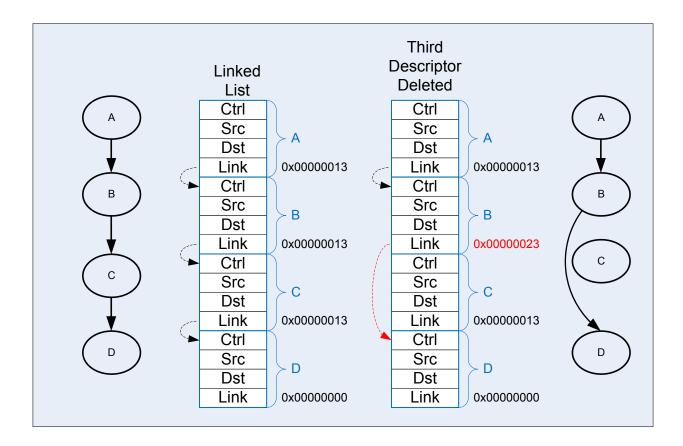

Figure 8.5. Descriptor Linked List

To start execution of the linked list of descriptors:

- · Write the absolute address of the first descriptor to the LINKADR field of the LDMA_CH0_LINK register
- · Set the LINK bit of LDMA CH0 LINK register.
- Configure the LDMA_CH0REQSEL register for the desired peripheral or select none for memory-to-memory
- · Clear and enable interrupts as desired
- · Set bit 0 in the LDMA LINKLOAD register to initiate loading and execution of the first descriptor

Alternativley, software can manually copy the first descriptor contents to the LDMA_CH0_CTRL, LDMA_CH0_SRC, LDMA_CH0_DST, and LDMA_CH0_LINK registers and then enable the channel in the LDMA_CHEN register.

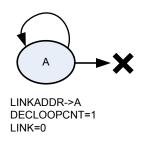

8.4.3 Single Descriptor Looped Transfer

This example demonstrates how to use looping using a single descriptor. This method allows a single DMA transfer to be repeated a specified number of times. The looping descriptor is stored in memory and reloaded by hardware. After a specified number of iterations, the transfer stops.

CH0 is setup to copy 4 words from the ADC FIFO into a 15 word buffer at 0x1000. It repeats 4 times to fill the entire 16 word buffer. An interrupt will fire when the entire 16 words have been transferred.

Initialize the Linked descriptor in memory as follows:

- · Configure CTRL member
 - DSTMODE = 0 (absolute)
 - SRCMODE = 0 (absolute)
 - SIZE = WORD
 - DSTINC = 0 (1 WORD)
 - SRCINC = 3 (0 WORDS)
 - · DECLOOPCNT=1 (decrement loop count)
 - REQMODE=1 (Use XFERCNT)
 - BLOCKSIZE = 4 (4 words)
 - BYTESWAP=0 (no swap)
 - XFERCNT= 4 (4 words)
 - STRUCTTPYE=0 (TRANSFER)
 - IGNORESREQ=1 (ignore single requests)
- Write the address ADC0_SINGLEDATA register to the SRC member
- · Write 0x1000 address to DST member
- · Configure the LINKLink member
 - LINK = 0 (stop after loop)
 - MODE = 1 (relative link address)
 - LINKADDR = 0 (point to ourself)
- · Configure the Channel
 - · Write the desired number of repeats to the LDMA CH0 LOOP register
 - SOURCESEL in LDMA_CH0REQSEL = ADC0 (select the ADC)
 - SIG in LDMA_CH0REQSEL = ADC0SCAN (select the scan conversion request)
- · Clear and enable interrupts
- Load the descriptor using LINKLOAD as described in 8.4.2 Descriptor Linked List

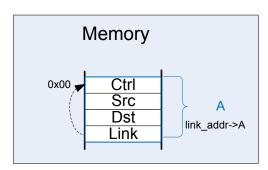

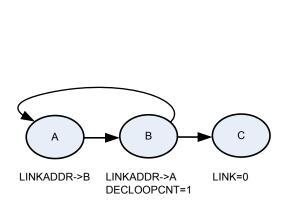

Figure 8.6. Single Descriptor Looped Transfer

Note that the looping descriptor must be stored in memory, because it must load itself from the link address in memory on each iteration.

8.4.4 Descriptor List With Looping

This example uses a descriptor list in memory with looping over multiple descriptors. This example also uses the looping feature and continues on with the next sequential descriptor after looping completes.

The descriptor list in memory is shown in figure Figure 8.7 Descriptor List With Looping on page 190. Descriptor A links to descriptor B. Descriptor B has the DECLOOPCNT bit enabled and loops back to the start of descriptor A. The LINK address of descriptor B is used for the loop address. The LINK bit is set to indicate that execution will continue after completion of looping. Once the LOOPCNT reaches zero, the LDMA will load descriptor C. Descriptor C must be located immediately following descriptor B.

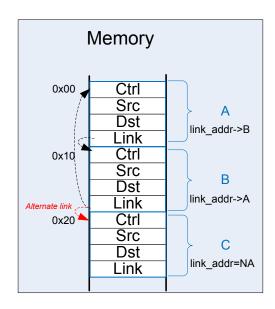

Figure 8.7. Descriptor List With Looping

Initialization is similar to the single looping descriptor with the following modifications.

- · Set the LINK bit in descriptors A and B
- · write the address of descriptor A into the LIKADDRESS of descriptor B
- · write the address of descriptor B into the LIKADDRESS of descriptor A
- · Descriptor C must be located immediately after descriptor B in memory

8.4.5 Simple Inter-Channel Synchronization

The LDMA controller features synchronization structures which allow differing channels and/or hardware events to pause a DMA sequence, and wait for a synchronizing event to restart it.

In this example DMA channel 0 and 1 are tasked with the transfer of different sets of data. Channel 0 has two transfer structures, and channel 1 just one, but channel 0 must wait until channel 1 has completed its transfer before it starts its second transfer structure.

Pausing channel 0 is accomplished by inserting a sync wait structure between the two transfer structures. This sync structure waits on SYNCTRIG[7] to be set by a sync set/clear structure which is controlled by channel 1. Sync structures do not transfer data, they can only set, clear, or wait to match the SYNCTRIG[7:0] bits. Note that sync structures cannot decrement loop counter.

```
LDMA SYNC
    SYNCTRIG=0x0 (at time 0)
LDMA_CH0
    Structure A @ 0x00
                                    Structure B @ 0x10
                                                                         Structure C @ 0x20
    CTRL
                                        CTRL
                                                                             CTRL
       STRUCTTYPE=XFER
                                            STRUCTTYPE=SYNC
                                                                                 STRUCTTYPE=XFER
    T.TNK
                                        T.TNK
                                                                             LINK
        LINKADDR[29:0]=0x00000004
                                            LINKADDR[29:0]=0x00000008
                                                                                 LINKADDR[29:0]=NA
        LINK=1
                                             LINK=1
                                                                                 LINK=0
                                        DST
                                            MATCHEN=0×80
                                             MATCHVAL=0x80 (waits for SYNCTRIG[7]=1)
LDMA_CH1
    Structure Y @ 0x30
                                    Structure Z @ 0x40
                                         CTRL
    CTRL
        STRUCTTYPE=XFER
                                             STRUCTTYPE=SYNC
    LINK
                                         LINK
        LINKADDR[29:0]=0x00000010
                                             LINKADDR=NA
                                             LINK=0
                                         SRC
                                             SRCCLR=0x0
                                             SRCSET=0x80 (sets SYNCTRIG[7])
```

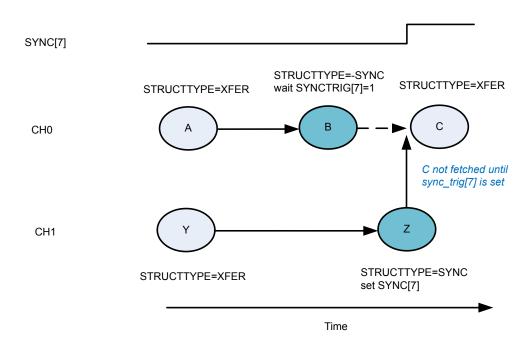

Figure 8.8. Simple Intra-channel Synchronization Example

Both A and Y effectively start at the same time. A finishes earlier, then it links to B, which waits for the SYNCTRIG[7] bit to be set before loading C. Y finishes after B is loaded, and it links to sync structure Z, which sets the SYNCTRIG[7] bit. Channel 0 responds to the trigger set by loading C for the final data transfer.

8.4.6 2D Copy

The LDMA can easily perform a 2D copy using a descriptor list with looping. This set up is visualized in Figure 8.9 2D Copy on page 193

For an application working with graphics, this would mean the ability to copy a rectangle of a given width and height from one picture to another.

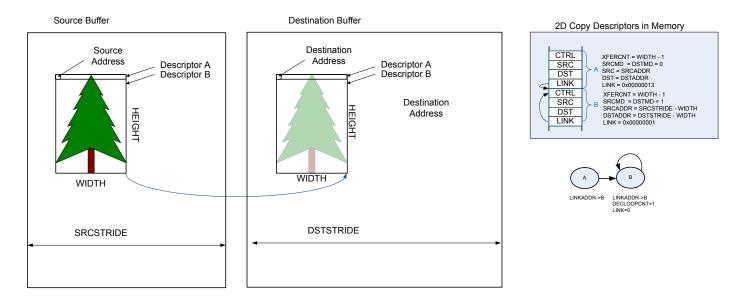

Figure 8.9. 2D Copy

The first descriptor will use absolute addressing mode and the source and destination addresses should point to the desired target addresses. The first descriptor will copy only the first row. The XFERCNT of the first descriptor is set to the desired width minus one.

- CTRL
 - XFERCNT = WIDTH 1
 - SRCMD = 0 (absolute)
 - DSTMD = 0 (absolute)
- SRCADDR = target source address
- DSTADDR = target destination address
- LINK = 0x00000013
 - LINK=1
 - LINKMD=1
 - LINKADDR=0x00000010 (point to next descriptor)

The second descriptor will use relative addressing and the source and destination addresses are set to the desired offset. After the completion of the first descriptor, the address registers will point to the last address transferred. Thus, the width must be subtracted from the stride to get the offset. The second descriptor uses looping and the link register has not offset.

- CTRL
 - XFERCNT = WIDTH 1
 - SRCMD = 1 (relative)
 - DSTMD = 1 (relative)
 - DECLOOPCNT = 1
- · SRCADDR = desired source offset (SRCSTRIDE-WIDTH)
- DSTADDR = desired destination offset (DSTSTRIDE-WIDTH)
- LINK = 0x00000001
 - LINK=0
 - LINKMD=1 (relative)
 - LINKADDR=0x000000000 (no offset)

Because the first descriptor already transferred one row, the number of looping repeats should be the desired height minus two. Therefore, LOOPCNT should be set to HEIGHT minus two before initiating the transfer.

This same method is easily extended to copy multiple rectangles by linking descriptors together. To initialize the LDMA_CHx_LOOP register, precede each descriptor pair described above with a write immediate descriptor which writes the desired value to the LOOPCNT field of the LDMA_CHx_LOOP register.

8.4.7 Ping-Pong

Communication peripherals often use ping-pong buffers. Ping-pong buffers allow the CPU to process data in one buffer while a peripheral transmits or receives data in the other buffer.

Both transmit and receive ping-pong buffers are easily implemented using the LDMA. In either case, this requires two descriptors as shown in Figure 8.10 Infinite Ping-Pong Example on page 195. The LINKADDR field of the LINK member should point to the other descriptor. Using two adjacent descriptors and relative link addressing ensures the descriptors are easily reloadable.

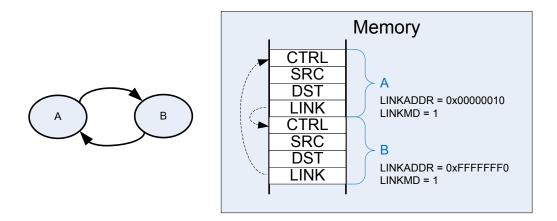

Figure 8.10. Infinite Ping-Pong Example

A **receiver** ping-pong buffer controller consists of two buffers and two descriptors stored in memory that point to the two buffers. Once initialized, as the peripheral receives data, it will fill the first buffer. Once the first buffer is full, it will link automatically to the second buffer and generate an interrupt. Software will then process the data in the first buffer while the LDMA is transferring data to the second buffer. For a receiver ping-pong buffer each descriptor should link to the other descriptor. The link bit should be set to provide infinite ping pong between the two buffers. The DONIFS bit in each descriptor should be set to generate an interrupt on the completion of each descriptor.

- · Descriptor A
 - CTRL
 - DONEIFS = 1
 - · other settings as desired
 - SRCADDR = peripheral source address
 - DSTADDR = memory destination address
 - LINK = 0x00000013
 - LINKADDR = 0x00000010 (next descriptor)
 - LINK = 1 (link to next descriptor)
 - LINKMD = 1 (relative addressing)
- Descriptor B
 - CTRL
 - DONEIFS = 1
 - · other settings as desired
 - SRCADDR = peripheral source address
 - DSTADDR = memory destination address
 - LINK = 0xFFFFFF3
 - LINKADDR = 0xFFFFFFF0 (previous descriptor)
 - LINK = 1 (link to previous descriptor)
 - LINKMD = 1 (relative addressing)

For **transmitter** ping-pong buffer, software will fill the first buffer and then initiate the DMA transfer. The LDMA will transmit the first buffer data while software is filling the second buffer. In this case, the two descriptors should point to each other, but not automatically

continue to the second buffer. The LINK bit should be cleared to zero. Once software has loaded the first buffer, it will use the LINK-LOAD bit to load the first descriptor and transmit the data. The DONIFS need not be set in each descriptor. The DMA will stop and then generate an interrupt at the completion of each descriptor.

- · Descriptor A
 - CTRL
 - DONEIFS = 0
 - · other settings as desired
 - SRCADDR = memory source address
 - DSTADDR = peripheral destination address
 - LINK = 0x00000013
 - LINKADDR = 0x00000010 (next descriptor)
 - LINK = 0 (link to next descriptor)
 - LINKMD = 1 (relative addressing)
- · Descriptor B
 - CTRL
 - DONEIFS = 0
 - · other settings as desired
 - · SRCADDR = memory source address
 - DSTADDR = peripheral destination address
 - LINK = 0xFFFFFF3
 - LINKADDR = 0xFFFFFF0 (previous descriptor)
 - LINK = 0 (link to previous descriptor)
 - LINKMD = 1 (relative addressing)

8.4.8 Scatter-Gather

Scatter-Gather in general refers to a process that copies data from multiple locations scattered in memory and gathers the data to a single location in memory, or vice versa. A simple descriptor list allows data gathering. For example, data from a discontiguous list of buffers might be copied to a contiguous sequential array of buffers. The inverse is also possible when a sequential array of buffers is scattered to a discontiguous list of available buffers. See section 8.4.2 Descriptor Linked List.

Some DMAs which only have two descriptors implement scatter-gather by using one descriptor to modify the other descriptor. While it is possible to implement this same behavior using the LDMA, it is much more straight-forward to just use a simple descriptor list.

8.5 Register Map

The offset register address is relative to the registers base address.

Bit	Name	Reset	Access	Description
31	DSTMODE	0	R	Destination Addressing Mode

This field specifies the destination addressing mode of linked descriptors. After loading a linked descriptor, reading this field will indicate the destination addressing mode of the linked descriptor. Note that the first descriptor always uses absolute addressing mode.

Value	Mode		Description
0	ABSOLUTE		The DSTADDR field of LDMA_CHx_DST contains the absolute address of the destination data.
1	RELATIVE		The DSTADDR field of LDMA_CHx_DST contains the relative offset of the destination data.
SRCMODE	0	R	Source Addressing Mode

This field specifies the source addressing mode of linked descriptors. After loading a linked descriptor, reading this field will indicate the source addressing mode of the linked descriptor. Note that the first descriptor always uses absolute addressing mode.

DSTINC	0x0	RWH	Destination Address Increment Size
1	RELATIVE		The SRCADDR field of LDMA_CHx_SRC contains the relative offset of the source data.
0	ABSOLUTE		The SRCADDR field of LDMA_CHx_SRC contains the absolute address of the source data.
Value	Mode		Description

This bit-field specifies the stride or number of unit data addresses to increment the destination address after each unit of data is transferred. The unit data width is controlled by the SIZE bit-field and can be a byte, half-word or word.

Value	Mode	Description
0	ONE	Increment destination address by one unit data size after each write
1	TWO	Increment destination address by two unit data sizes after each write
2	FOUR	Increment destination address by four unit data sizes after each write
3	NONE	Do not increment the destination address. Writes are made to a fixed destination address, for example writing to a FIFO.

9. RMU - Reset Management Unit

Quick Facts

What?

The RMU ensures correct reset operation. It is responsible for connecting the different reset sources to the reset lines of the EFR32xG12 Wireless Gecko.

Why?

A correct reset sequence is needed to ensure safe and synchronous startup of the EFR32xG12 Wireless Gecko. In the case of error situations such as power supply glitches or software crash, the RMU provides proper reset and startup of the EFR32xG12 Wireless Gecko.

How?

The Power-on Reset and Brown-out Detector of the EFR32xG12 Wireless Gecko provides power line monitoring with exceptionally low power consumption. The cause of the reset may be read from a register, thus providing software with information about the cause of the reset.

9.1 Introduction

The RMU is responsible for handling the reset functionality of the EFR32xG12 Wireless Gecko.

9.2 Features

- · Reset sources
 - Power-on Reset (POR)
 - Brown-out Detection (BOD) on the following power domains:
 - · Analog Unregulated Power Domain AVDD
 - · Digital Unregulated Power Domain DVDD
 - · Regulated Digital Domain DECOUPLE (DEC)
 - · RESETn pin reset
 - · Watchdog reset
 - Software triggered reset (SYSRESETREQ)
 - · Core LOCKUP condition
- · EM4 Hibernate/Shutoff Detection
- EM4 Hibernate/Shutoff wakeup reset from GPIO pin
- · Configurable reset levels
- · A software readable register indicates the cause of the last reset

9.3 Functional Description

The RMU monitors each of the reset sources of the EFR32xG12 Wireless Gecko. If one or more reset sources go active, the RMU applies reset to the EFR32xG12 Wireless Gecko. When the reset sources go inactive the EFR32xG12 Wireless Gecko starts up. At startup the EFR32xG12 Wireless Gecko loads the stack pointer and program entry point from memory, and starts execution. Figure 9.1 RMU Reset Input Sources and Connections on page 219 shows an overview of the reset system on EFR32xG12 Wireless Gecko.

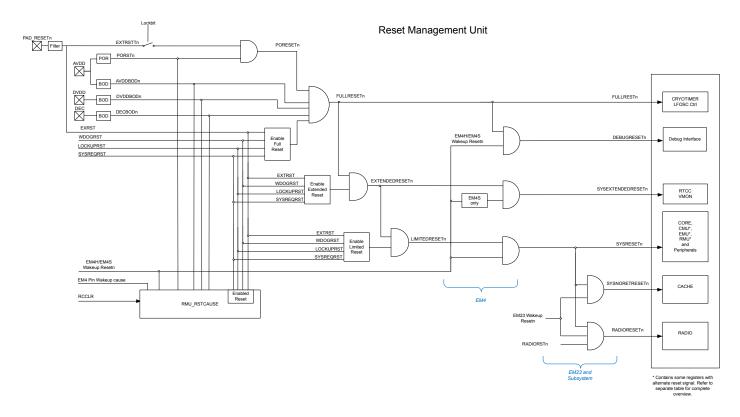

Figure 9.1. RMU Reset Input Sources and Connections

9.3.1 Reset Levels

The reset sources on EFR32xG12 Wireless Gecko can be divided in two main groups; Hard resets and Soft resets.

The soft resets can be configured to be either DISABLED, LIMITED, EXTENDED or FULL. The reset level for soft reset sources is configured in the xxxRMODE bitfields in RMU_CTRL.

Table 9.1. Reset Levels

RMU_CTRL_xxxRMODE	Parts of System Reset
DISABLED	Nothing is reset, request will not be registered in RMU_RSTCAUSE
LIMITED	Everything reset, with exception of CRYOTIMER, DEBUGGER, RTCC, VMON and parts of CMU, RMU and EMU.
EXTENDED	Everything reset, with exception of CRYOTIMER, DEBUGGER, and parts of CMU, RMU and EMU.
FULL	Everything reset, with exception of some registers in RMU and EMU.

The reset sources resulting in a soft reset are:

- · Watchdog reset
- · Lockup reset
- · System reset request
- Pin reset (Pin reset can be configured to be either a soft or a hard reset, see 9.3.5 RESETn Pin Reset for details.)

Note: LIMITED and EXTENDED resets are synchronized to HFSRCCLK. If HFSRCCLK is slow, there will be latency on reset assertion. If HFSRCCLK is not running, reset will be asserted after a timeout.

Hard resets will reset the entire chip, the reset sources resulting in a hard reset are:

- Power-on reset
- · Brown-out reset
- Pin reset (Pin reset can be configured to be either a soft or a hard reset, see 9.3.5 RESETn Pin Reset for details.)

9.3.2 RMU_RSTCAUSE Register

Whenever a reset source is active, the corresponding bit in the RMU_RSTCAUSE register is set. At startup the program code may investigate this register in order to determine the cause of the reset. The register is cleared upon POR and software write to RMU_CMD_RCCLR. The register should be cleared after the value has been read at startup, otherwise the register may indicate multiple causes for the reset at next startup.

RMU_RSTCAUSE should be interpreted according to Table 9.2 RMU Reset Cause Register Interpretation on page 221. In Table 9.2 RMU Reset Cause Register Interpretation on page 221, the reset causes are ordered by severity from right to left. A reset cause bit is invalidated (i.e. can not be trusted) if one of the bits to the right of it does not match the table. X bits are don't care.

Note: It is possible to have multiple reset causes. For example, an external reset and a watchdog reset may happen simultaneously.

Table 9.2. RMU Reset Cause Register Interpretation

RMU_R	STCAUS	E							Reset cause
EM4RST	WDOGRST	SYSREQRST	LOCKUPRST	EXTRST	DECBOD	DVDDBOD	AVDDBOD	PORST

1. Pin	reset cor	nfigured a	s hard/so	oft	1	1		1	1

9.3.3 Power-On Reset (POR)

The POR ensures that the EFR32xG12 Wireless Gecko does not start up before the AVDD supply voltage has reached the threshold voltage VPORthr (roughly 1.2V). Before the POR threshold voltage is reached, the EFR32xG12 Wireless Gecko is kept in reset state. The operation of the POR is illustrated in Figure 9.2 RMU Power-on Reset Operation on page 222, with the active low POWERONn reset signal. The reason for the "unknown" region is that the corresponding supply voltage is too low for any reliable operation.

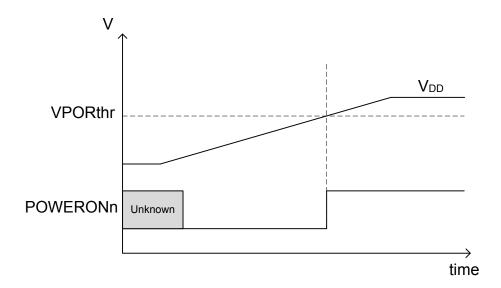

Figure 9.2. RMU Power-on Reset Operation

9.3.4 Brown-Out Detector (BOD)

The EFR32xG12 Wireless Gecko has 3 brownout detectors, one for the unregulated power (DVDD), one for the regulated internal power (DECOUPLE), and one for the Analog Power Domain (AVDD). The BODs are constantly monitoring these supply voltages. Whenever the unregulated or regulated power drops below the VBODthr value (see the Electrical Characteristics section of the data sheet for details), or if AVDD drops below the voltage at the DECOUPLE pin, the corresponding active low BROWNOUTn line is held low. The BODs also include hysteresis, which prevents instability in the corresponding BROWNOUTn line when the supply is crossing the VBODthr limit or the AVDD supply drops below the DECOUPLE pin. The operation of the BOD is illustrated in Figure 9.3 RMU Brownout Detector Operation on page 222. The "unknown" regions are handled by the POR module.

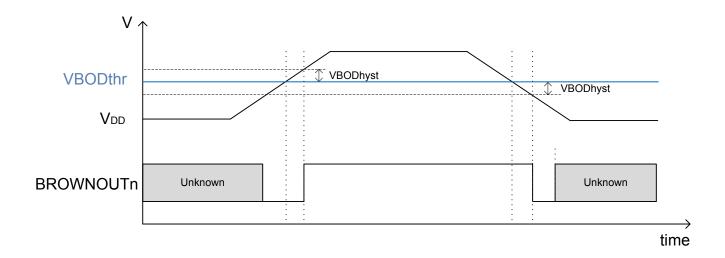

Figure 9.3. RMU Brown-out Detector Operation

9.3.5 RESETn Pin Reset

The pin reset on EFR32xG12 Wireless Gecko can be configured to be either hard or soft. By default, pin reset is configured as a soft reset source. To configure it as a hard reset, clear the PINRESETSOFT bit in CLW0 in the Lock bit page, see 7.3.2 Lock Bits (LB) Page Description for details. Forcing the RESETn pin low generates a reset of the EFR32xG12 Wireless Gecko. The RESETn pin includes an on-chip pull-up resistor, and can therefore be left unconnected if no external reset source is needed. Also connected to the RESETn line is a filter which prevents glitches from resetting the EFR32xG12 Wireless Gecko.

9.3.6 Watchdog Reset

The Watchdog circuit is a timer which (when enabled) must be cleared by software regularly. If software does not clear it, a Watchdog reset is activated. This functionality provides recovery from a software stalemate. Refer to the Watchdog section for specifications and description. The Watchdog reset can be configured to cause different levels of reset as determined by WDOGRMODE in the RMU CTRL register.

9.3.7 Lockup Reset

A Cortex-M4 lockup is the result of the core being locked up because of an unrecoverable exception following the activation of the processor's built-in system state protection hardware.

A Cortex-M4 lockup gives immediate indication of seriously errant kernel software. This is the result of the core being locked up due to an unrecoverable exception following the activation of the processor's built in system state protection hardware. For more information about the Cortex-M4 lockup conditions see the ARMv7-M Architecture Reference Manual. The Lockup reset does not reset the Debug Interface, unless configured as a FULL reset. The Lockup reset can be configured to cause different levels of reset as determined by the LOCKUPRMODE bits in the RMU_CTRL register. This includes disabling the reset.

9.3.8 System Reset Request

Software may initiate a reset (e.g. if it finds itself in a non-recoverable state). By asserting the SYSRESETREQ in the Application Interrupt and Reset Control Register, a reset is issued. The SYSRESETREQ does not reset the Debug Interface, unless configured as a FULL reset. The SYSRESTREQ reset can be configured to cause different levels of reset as determined by SYSRESETRMODE bits in the RMU_CTRL register. This includes disabling the reset.

9.3.9 Reset State

The RESETSTATE bitfield in RMU_CTRL is a read-write register intended for software use only, and can be used to keep track of state throughout a reset. This bitfield is only reset by POR and hard pin reset.

9.3.10 Register Reset Signals

Figure 9.1 RMU Reset Input Sources and Connections on page 219 shows an overview of how the different parts of the design are affected by the different levels of reset. For RMU, EMU and CMU there are some exceptions. These are given in the following tables.

9.3.10.1 Registers With Alternate Reset

Table 9.3. Alternate Reset for Registers in RMU

RMU Reset Levels						
POR and hard pin reset	RMU_CTRL_WDOGRMODE					
	RMU_CTRL_LOCKUPRMODE					
	RMU_CTRL_SYSRMODE					
	RMU_CTRL_PINRMODE					
	RMU_CTRL_RESETSTATE					
FULL reset	RMU_LOCK_LOCKKEY					

Table 9.4. Alternate Reset for Registers in CMU

CMU Reset Levels	
FULL reset	CMU_LFRCOCTRL
	CMU_LFXOCTRL
EXTENDED reset	CMU_LFECLKSEL
	CMU_LFECLKEN0
	CMU_LFEPRESC0

Table 9.5. Alternate Reset for Registers in EMU

EMU Reset Levels

## 10. EMU - Energy Management Unit

#### **Quick Facts**

#### What?

The EMU (Energy Management Unit) handles the different low energy modes in EFR32xG12 Wireless Gecko

#### Why?

The need for performance and peripheral functions varies over time in most applications. By efficiently scaling the available resources in real time to match the demands of the application, the energy consumption can be kept at a minimum.

#### How?

With a broad selection of energy modes, a high number of low-energy peripherals available even in EM2 Deep Sleep, and short wake-up time (3 µs from EM2 Deep Sleep and EM3 Stop), applications can dynamically minimize energy consumption during program execution.

#### 10.1 Introduction

The Energy Management Unit (EMU) manages all the low energy modes (EM) in EFR32xG12 Wireless Gecko. Each energy mode manages whether the CPU and the various peripherals are available. The energy modes range from EM0 Active to EM4 Shutoff. EM0 Active mode provides the highest amount of features, enabling the CPU, Radio, and peripherals with the highest clock frequency. EM4 Shutoff Mode provides the lowest power state, allowing the part to return to EM0 Active on a wake-up condition. The EMU also controls the various power routing configurations, internal regulators settings, and voltage monitoring needed for optimal power configuration and protection.

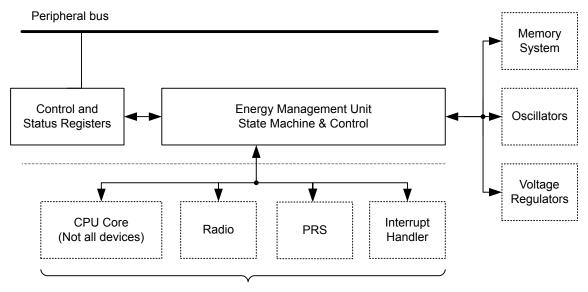

#### 10.2 Features

The primary features of the EMU are listed below:

- · Energy Modes control
  - · Entry into EM4 Hibernate or EM4 Shutoff
  - · Configuration of regulators and clocks for each Energy Mode
  - · Configuration of various EM4 Hibernate/Shutoff wake-up conditions
  - · Configuration of RAM power and retention settings
  - · Configuration of GPIO retention settings
- · Power routing configurations
  - DCDC control
  - · Internal power switches allowing for extensible system power architecture
- · Temperature measurement control and status
- · Brown Out Detection
- · Voltage Monitoring
  - · Four dedicated continuous monitor channels
  - · Optional monitor features include interrupt generation and low power mode wake-up
- · State Retention
- · Voltage Scaling
  - EM0/EM1 voltage scaling
  - EM2/EM3 voltage scaling
  - · EM4H voltage scaling

### 10.3 Functional Description

The EMU is responsible for managing the wide range of energy modes available in EFR32xG12 Wireless Gecko. The block works in harmony with the entire platform to easily transition between energy modes in the most efficient manner possible. The following diagram Figure 10.1 EMU Overview on page 233, shows the relative connectivity to the various blocks in the system.

The combined state of these modules defines the required energy mode

Figure 10.1. EMU Overview

The EMU is available on the peripheral bus. The energy management state machine controls the internal voltage regulators, oscillators, memories, and interrupt system. Events, interrupts, and resets can trigger the energy management state machine to return to the active state. This is further described in the following sections.

The power architecture is highly configurable to meet system power performance needs. Several external power configurations are supported. The EMU allows flexible control of internal DCDC, digital LDO regulator, and internal power switching.

#### 10.3.1 Energy Modes

EFR32xG12 Wireless Gecko features six main energy modes, referred to as Energy Mode 0 (EM0 Active) through Energy Mode 4 (EM4 Shutoff). The Cortex-M4 is only available for program execution in EM0 Active. In EM0 Active/EM1 Sleep any peripheral function can be enabled. EM2 Deep Sleep through EM4 Shutoff, also referred to as low energy modes, provide a significantly reduced energy consumption while still allowing a rich set of peripheral functionality. The following Table 10.1 table on page 234 shows the possible transitions between different energy modes.

Table 10.1. Energy Mode Transitions

Current Mode	EM Transition	Action				
	Enter EM0 Active	Enter EM1 Sleep	Enter EM2 Deep Sleep	EnterEM3 Stop	EnterEM4 Hi- bernate	Enter EM4 Shutoff
EM0 Active		Sleep (WFI, WFE)	Deep Sleep (WFI, WFE)	Deep Sleep (WFI, WFE)	EM4 Entry	EM4 Entry
EM1 Sleep	IRQ		Peripheral wake up done ¹	Peripheral wake up done ¹		
EM2 Deep Sleep	IRQ	Peripheral wake up req ¹				
EM3 Stop	IRQ	Peripheral wake up req ¹				
EM4 Hibernate	Wake Up					
EM4 Shutoff	Wake Up					
	•	1	1	•	•	•

#### Note:

The CSEN, LESENSE, ADC, RAC, and LEUART have the ability to temporarily wake up the part from either EM2 Deep Sleep or EM3 Stop to EM1 Sleep in order to transfer data. Once completed, the part is automatically placed back into the EM2 Deep Sleep or EM3 Stop mode.

The Core can always request to go to EM1 Sleep with the WFI or WFE command during EM0 Active. The core will be prevented from entering EM2 Deep Sleep or EM3 Stop if the RAC is transferring data or if Flash is programming or erasing.

An overview of supported energy modes and available functionality is shown in Table 10.2 EMU Energy Mode Overview on page 234. For each energy mode, the system will typically default to its lowest power configuration, with non-essential clocks and peripherals disabled. Functionality may be then selectively enabled by software.

Table 10.2. EMU Energy Mode Overview

GPIO Pin State Retention	Yes	Yes	Yes	Available ¹⁰	Available ¹⁰

#### Note:

- 1. Approximate time. Refer to the data sheet
- 2. Leaving the debugger connected when in EM2 or EM3 will cause the system to enter a higher power EM2 mode in which the high frequency clocks are still enabled and certain core functionality is still powered-up in order to maintain debug-functionality.
- 3. The LDMA can be used with some low power peripherals (e.g., ADC, LEUART, LESENSE, CSEN) in EM2/3. Features required by the LDMA which are not supported in EM2/3 (e.g., HFCLK), will be automatically enabled prior to the LDMA transfer and then automatically disabled afterwards.
- 4. The RAC can be woken via a PRS interrupt to EM1 to transfer data. Once complete, the system will return to EM2.
- 5. While in EM2/3, an asynchronous event can be routed through PRS (e.g. GPIO IRQ or ACMP output) to wake up the ADC. Features required by the ADC which are not supported in EM2/3 (e.g., AUXHFRCO) will be automatically enabled to allow the ADC to convert a sample, and then automatically disabled afterwards.
- 6. I2C functionality limited to receive address recognition
- 7. Must be using ULFRCO
- 8. ACMP functionality in EM2/3 limited to edge interrupt
- 9. Pin wake-up in EM4 supported only on GPIO_EM4WUx pins. Consult data sheet for complete list of pins.
- 10. If enabled in EMU->EM4CTRL.EM4IORETMODE.
- 11. Available only when the ULFRCO is the LFBCLK source.

The different energy modes are summarized in the following sections.

#### 10.3.1.1 EM0 Active

EM0 Active provides all system features.

- · Cortex-M4 is executing code
- · Radio functionality is available
- · High and low frequency clock trees are active
- · All oscillators are available
- · All peripheral functionality is available

## 10.3.1.2 EM1 Sleep

EM1 Sleep disables the core but leaves the remaining system fully available.

- · Cortex-M4 is in sleep mode. Clocks to the core are off
- · Radio functionality is available
- · High and low frequency clock trees are active
- · All oscillators are available
- · All peripheral functionality is available

#### 10.3.1.3 EM2 Deep Sleep

This is the first level into the low power energy modes. Most of the high frequency peripherals are disabled or have reduced functionality. Memory and registers retain their values.

- · Cortex-M4 is in sleep mode. Clocks to the core are off.
- · High frequency clock tree is inactive
- · Low frequency clock tree is active
- · The following oscillators are available
  - LFRCO, LFXO, ULFRCO, AUXHFRCO (on demand, if used by the ADC)
- The following low frequency peripherals are available
  - RTCC, WDOG, LEUART, LETIMER, LESENSE, PCNT, CRYOTIMER
- The following analog peripherals are available (with potential limitations on functionality)
  - · ADC, IDAC, VDAC, OPAMP, CSEN
- · Wake-up to EM0 Active through
  - Peripheral interrupt, reset pin, power on reset, asynchronous pin interrupt, I2C address recognition, or ACMP edge interrupt
- · Wake-up to EM1 Sleep through
  - · RAC data transfer request
  - · Part returns to EM2 Deep Sleep when transfers are complete
- · RAM and register values are preserved
  - RAM blocks may be optionally powered down for lower power
- · GPIO pin state is retained
- · RTCC memory is retained
- The DC-DC converter can be configured to remain on in low-power mode.

#### 10.3.1.4 EM3 Stop

In this low energy mode, all low frequency oscillators (LFXO, LFRCO) and all low frequency clocks derived from them, are stopped, as well as all high frequency clocks. Most peripherals are disabled or have reduced functionality. Memory and registers retain their values.

- · Cortex-M4 is in sleep mode. Clocks to the core are off.
- · High frequency clock tree is inactive
- · All low frequency clock trees derived from the low frequency oscillators (LFXO, LFRCO) are inactive
- · The following oscillators are available
  - ULFRCO, AUXHFRCO (on demand, if used by the ADC)
- The following low frequency peripherals are available if clocked by the ULFRCO
  - RTCC, WDOG, CRYOTIMER
- · The following analog peripherals are available (with potential limitations on functionality)
  - ADC, IDAC, VDAC, OPAMP, CSEN
- · Wake-up to EM0 Active through
  - Peripheral interrupt, reset pin, power on reset, asynchronous pin interrupt, I2C address recognition, or ACMP edge interrupt
- · Wake-up to EM1 Sleep through
  - · RAC data transfer request
  - · Part returns to EM3 Stop when transfers are complete
- RAM and register values are preserved
  - · RAM blocks may be optionally powered down for lower power
- · GPIO pin state is retained
- · RTCC memory is retained
- The DC-DC converter can be configured to remain on in low-power mode.

#### 10.3.1.5 EM4 Hibernate

The majority of peripherals are shutoff to reduce leakage power. A few selected peripherals are available. System memory and registers do not retain values. GPIO PAD state and RTCC RAM are retained. Wake-up from EM4 Hibernate requires a reset to the system, returning it back to EM0 Active

- · Cortex-M4 is off
- · High frequency clock tree is off
- · Some low frequency clock trees may be active
- · The following oscillators are available
  - · LFRCO, LFXO, ULFRCO
- · The following low frequency peripherals are available
  - · RTCC, CRYOTIMER
- Wake-up to EM0 Active through
  - VMON, EMU temperature sensor, RTCC, CRYOTIMER, reset pin, power on reset, and asynchronous pin interrupt (on GPIO_EM4WUx pins only)
- GPIO pin state may be retained (depending on EMU->EM4CTRL.EM4IORETMODE configuration)
- RTCC memory is retained
- The DC-DC converter can be configured to remain on in low-power mode.

#### 10.3.1.6 EM4 Shutoff

EM4 Shutoff is the lowest energy mode of the part. There is no retention except for GPIO PAD state. Wake-up from EM4 Shutoff requires a reset to the system, returning it back to EM0 Active

- · Cortex-M4 is off
- · High frequency clock tree is off
- · Low frequency clock tree may be active
- · The following oscillators are available
  - LFRCO, LFXO, ULFRCO
- · The following low frequency peripherals are available
  - CRYOTIMER
- · Wake-up to EM0 Active through
  - CRYOTIMER, reset pin, power on reset, and asynchronous pin interrupt (on GPIO_EM4WUx pins only)
- GPIO pin state may be retained (depending on EMU->EM4CTRL.EM4IORETMODE configuration)
- The DC-DC converter configuration is reset to its default unconfigured configuration (DC-DC converter disabled and bypass switch is off)

#### 10.3.2 Entering Low Energy Modes

The following sections describe the requirements for entering the various energy modes.

**Note:** If Voltage scaling is being used to save system energy, it is important to ensure the proper conditions for entry and exit of EM2 Deep Sleep, EM3 Stop or EM4 Hibernate be met. See 10.3.9.2.1 EM2/EM3 Voltage Scaling Guidelines and 10.3.9.3.1 EM4H Voltage Scaling Guidelines for details.

#### 10.3.2.1 Entry Into EM1 Sleep

Energy mode EM1 Sleep is entered when the Cortex-M4 executes the Wait For Interrupt (WFI) or Wait For Event (WFE) instruction while the SLEEPDEEP bit the Cortex-M4 System Control Register is cleared. The MCU can re-enter sleep automatically out of an Interrupt Service Routine (ISR) if the SLEEPONEXIT bit in the Cortex-M4 System Control Register is set. Refer to ARM documentation on entering Sleep modes.

Alternately, EM1 Sleep can be entered from either EM2 Deep Sleep or EM3 Stop from a Peripheral Wake-up Request allowing transfers between the Peripheral and System RAM or Flash. On EFR32, ADC, CSEN, IDAC, LESENSE, and LEUART peripherals can request this wake-up event. Refer to their respective register specification to enable this option. The system will return back to EM2 Deep-Sleep or EM3 Stop once the ADC, CSEN, IDAC, LESENSE, or LEUART have completed its transfers and processing.

During Peripheral Wake-Up Request, additional system resources such as FLASH and other Peripherals can be enabled for access.

#### 10.3.2.2 Entry Into EM2 Deep Sleep or EM3 Stop

Energy mode EM2 Deep Sleep or EM3 Stop may be entered when all of the following conditions are true:

- · Radio RAC state machine is in OFF state
- · IDAC is currently not updating output.
- · Cortex-M4 (if present) is in DEEPSLEEP state
- · Flash Program/Erase Inactive
- · DMA done with all current requests
- · A debugger is not currently connected.

Entry into EM2 Deep Sleep and EM3 Stop can be blocked by setting the EMU CTRL->EM2BLOCK bit.

**Note:** When EM2 Deep Sleep or EM3 Stop entry is blocked, the part is not able to enter a lower energy state. The core will be in a sleep state, similar to EM1, where it is waiting for a proper interrupt of other valid wake-up event. Once the blocking conditions are removed, then the part will automatically enter a lower energy state.

Energy mode EM2 Deep Sleep is entered from EM0 Active when the Cortex-M4 executes the Wait For Interrupt (WFI) or Wait For Event (WFE) instruction while the SLEEPDEEP bit in the Cortex-M4 System Control Register is set. The MCU can re-enter DeepSleep automatically out of an Interrupt Service Routine (ISR) if the SLEEPONEXIT bit in the Cortex-M4 System Control Register is set. Refer to ARM documentation on entering Sleep modes.

Alternately, EM2 Deep Sleep or EM3 Stop is entered from EM1 Sleep upon the completion of a Peripheral Wake-Up Request from the RAC if no EM0 Active wake-up happens in the meantime.

#### 10.3.2.3 Entry Into EM4 Hibernate or EM4 Shutoff

Energy mode EM4 Hibernate and EM4 Shutoff is entered through register access.

Software must ensure no modules are active, such as RAC, when entering EM4 Hibernate/Shutoff. EM4CTRL->EM4STATE field must be configured to select either Hibernate (EM4H) or Shutoff (EM4S) mode prior to entering EM4.

Software may enter EM4 Hibernate/Shutoff from EM0 Active by writing the sequence 2,3,2,3,2,3,2,3,2 to EM4CTRL->EM4ENTRY bit field. If the EM4BLOCK bit in WDOGn_CTRL is set, the CPU will be prevented from entering EM4 Hibernate/Shutoff by software request.

An active debugger connection will prevent entry into EM4 Hibernate/Shutoff.

Note that upon entry into EM4 Shutoff, the DC-DC converter configuration is reset to its default (i.e. Unconfigured) configuration. In the Unconfigured configuration, the DC-DC converter will be disabled and the bypass switch will be turned off.

#### 10.3.3 Exiting a Low Energy Mode

A system in EM2 Deep Sleep and EM3 Stop can be woken up to EM0 Active through regular interrupt requests from active peripherals. Since state and RAM retention is available, the EFR32 is fully restored and can continue to operate as before it went into the Low Energy Mode.

Wake-Up from EM4 Hibernate or EM4 Shutoff is performed through reset. Wake-Up from a specific module must be enabled in that module's EM4WUEN register.

Enabled interrupts that can cause wake-up from a low energy mode are shown in Table 10.3 EMU Wake-Up Triggers from Low Energy Modes on page 240. The wake-up triggers always return the EFR32 to EMO Active/EM1 Sleep. Additionally, any reset source will return to EMO Active. VMON-based EM4 Hibernate wake-ups also set the corresponding rise or fall interrupt flag. These flags serve as the wake-up source for EM4 Hibernate and must be cleared by software on EM4 Hibernate exit. Not doing so will result in an immediate wake-up after next EM4 Hibernate entry.

Table 10.3. EMU Wake-Up Triggers from Low Energy Modes

Peripheral	Wake-Up Trigger	EM2 Deep Sleep	EM3 Stop	EM4 Hiber- nate	EM4 Shut- off
LEUART (Low Energy UART)	Receive / transmit	Yes	_	_	_
LETIMER	Any enabled interrupt	Yes	_	_	_
WDOG	Any enabled interrupt	Yes	Yes	_	_
LESENSE	Any enabled interrupt	Yes	_	_	_
LFXO	Ready Interrupt	Yes	_	_	_
LFRCO	Ready Interrupt	Yes	_	_	_
I ² C	Receive address recognition	Yes	Yes	_	_
ACMP	Any enabled edge interrupt	Yes	Yes	_	_
ADC	SINGLE / SCAN FIFO events, window comparator, and VREF overvoltage	Yes	Yes	_	_
CSEN	Wake on threshold	Yes	Yes	_	_
VDAC	Any enabled interrupt except EM23ERRIF	Yes	Yes	_	_
PCNT	Any enabled interrupt	Yes	Yes ¹	_	_
RTCC	Any enabled interrupt	Yes	Yes	Yes ²	
VMON	Rising or falling edge on any monitored power	Yes	Yes	Yes ²	_
EMU Temperature Sensor	Measured temperature outside the defined limits	Yes	Yes	Yes ²	_
CRYOTIMER	Timeout	Yes	Yes	Yes ²	Yes ²
Pin Interrupts	Transition	Yes	Yes	Yes ^{2, 3}	Yes ^{2, 3}
Reset Pin	Assertion	Yes	Yes	Yes	Yes
Power	Cycle Off/On	Yes	Yes	Yes	Yes

## Note:

- 1. When using an external clock
- 2. Corresponding bit in the module's EM4WUEN must be set.
- 3. Only available on a subset of the pins. Refer to the data sheet for details.

#### 10.3.4 Power Configurations

The EFR32xG12 Wireless Gecko allows several power configurations with additional options giving flexible power architecture selection.

In order to provide the lowest power consuming radio solutions, the EFR32xG12 Wireless Gecko comes with a DC-DC module to power internal circuits. The DC-DC requires an external inductor and capacitor (refer to the data sheet for recommended values).

The EFR32xG12 Wireless Gecko has multiple internal power domains: IO Supply (IOVDD), Analog & Flash (AVDD), RF Analog Supply (RFVDD), RF Power Amplifier Supply (PAVDD), Input to digital LDO (DVDD), and low-voltage digital supply (DECOUPLE). Additional detail for each configuration and option is given in the following sections.

When assigning supply sources, the following requirement must be adhered to:

- VREGVDD = AVDD (Must be the highest voltage in the system)
- VREGVDD >= DVDD
- VREGVDD >= PAVDD
- VREGVDD >= RFVDD
- VREGVDD >= IOVDD

The system boots up into a safe power state, but must be immediately programmed to the desired configuration by writing to the EMU_PWRCFG->PWRCFG bitfield. Out of POR, the PWRCFG is set to UNCONFIGURED, locking access to various power control registers. Once written, the PWRCFG cannot be changed.

## 10.3.4.1 Power Configuration 0: Unconfigured

Upon power-on reset (POR) or entry into EM4 Shutoff, the system is configured in a safe state that supports all of the available Power Configurations. The Unconfigured Configuration is shown in the simplified diagram below.

In the Unconfigured Configuration:

- The DC-DC converter's Bypass switch is off.
- The internal digital LDO is powered from the AVDD pin (i.e. REGPWRSEL=0 in EMU_PWRCTRL). Note the maximum allowable current into the LDO when REGPWRSEL=0 is 20 mA. For this reason, immediately after startup firmware should configure RE-GPWRSEL=1 to power the digital LDO from DVDD.
- The analog blocks are powered from the AVDD supply pin (i.e., ANASW=0 in EMU_PWRCTRL).

After power on, firmware can configure the device to based on the external hardware configuration. Note that the PWRCFG register can only be written once to a valid value and is then locked. This should be done immediately out of boot to select the proper power configuration. The DC-DC and PWRCTRL registers will be locked until the PWRCFG register is configured.

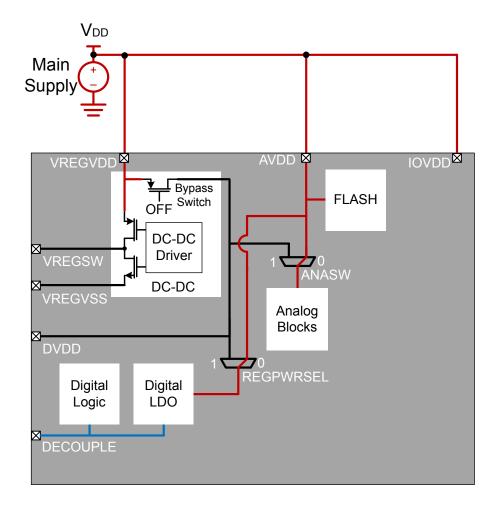

Figure 10.2. Unconfigured Power Configuration

#### 10.3.4.2 Power Configuration 1: No DC-DC

In Power Configuration 1, the DC-DC converter is programmed in off mode and the bypass switch is off. The DVDD pin must be powered externally - typically, DVDD is connected to the main supply. DVDD powers the internal digital LDO (i.e., REGPWRSEL=1) which powers the digital circuits. IOVDD and AVDD are powered from the main supply as well. RFVDD and PAVDD, which power the radio, are shorted to the main supply as well.

VREGSW must be left disconnected in this configuration.

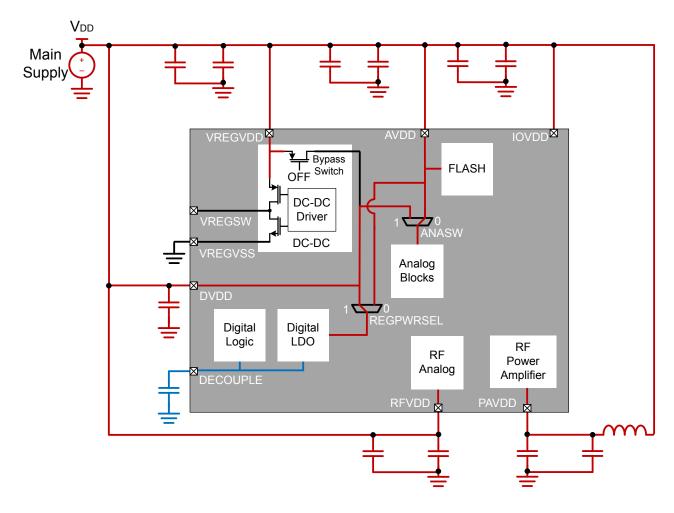

Figure 10.3. DC-DC Off Power Configuration

#### 10.3.4.3 Power Configuration 2: DC-DC

For the lowest power applications, the DC-DC converter can be used to power the DVDD supply, as well as RFVDD and PAVDD.

In Power Configuration 2, the DC-DC output ( $V_{DCDC}$ ) is connected to DVDD. DVDD powers the internal digital LDO (i.e., RE-GPWRSEL=1) which powers the digital circuits. AVDD is connected to the main supply voltage. The internal analog blocks may be powered from AVDD or DVDD, depending on the ANASW configuration. RFVDD and PAVDD are powered from  $V_{DCDC}$  as well.

IOVDD could be connected to either the main supply (as shown below) or to  $V_{DCDC}$ , depending on the system I/O requirements. Because  $V_{DCDC}$  will be unpowered (i.e., floating) at startup, if IOVDD is powered from the DC-DC converter then any circuit attached to IOVDD will not be powered until the DC-DC is configured (or the bypass switch is enabled). Refer to 10.3.8 IOVDD Connection section for further details and issues that may result when connecting IOVDD to  $V_{DCDC}$ .

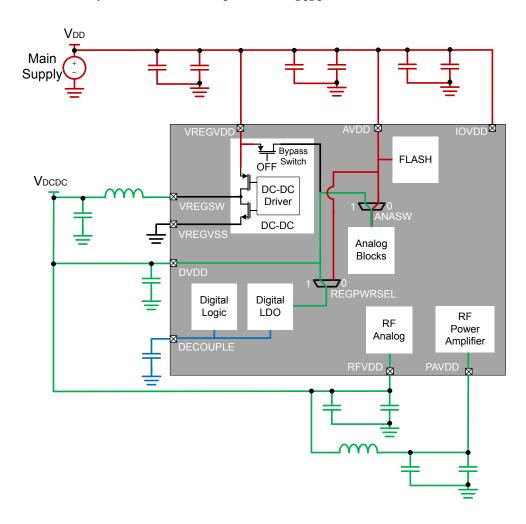

Figure 10.4. DC-DC Standard Power Configuration

As the main supply voltage approaches the DC-DC output voltage, it eventually reaches a point where becomes inefficient (or impossible) for the DC-DC module to regulate  $V_{DCDC}$ . At this point, firmware can enable bypass mode, which effectively disables the DC-DC and shorts the main supply voltage directly to the DC-DC output. If and when sufficient voltage margin on the main supply returns, the system can be switched back into DC-DC regulation mode.

An alternate "High RF Power" DC-DC configuration has the external main supply connected directly to the PAVDD. This configuration supports a higher transmit power (e.g., >13 dBm) required for some radio protocol specifications. No additional software setting is required for this mode. The following diagram shows an example of connecting PAVDD to the main supply while DVDD and RFVDD are connected to the filtered  $V_{DCDC}$ .

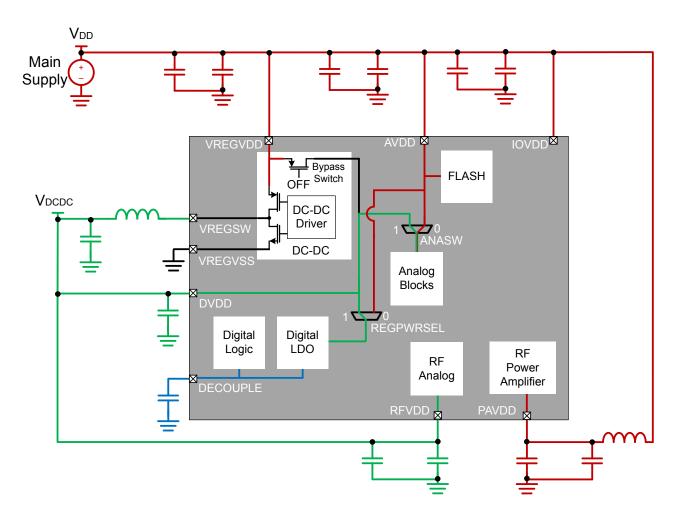

Figure 10.5. DC-DC High RF Power Configuration

# 10.3.5 DC-to-DC Interface

The EFR32xG12 Wireless Gecko devices feature a DC-DC buck converter which requires a single external inductor and a single external capacitor. The converter takes the VREGVDD input voltage and converts it down to an output voltage between VREGVDD and 1.8 V with a peak efficiency of approximately 90% in Low Noise (LN) mode and 85% in Low Power (LP) mode. Refer to the data sheet for full DC-DC specifications.

The DC-DC converter operates in either Low Noise (LN) or Low Power (LP) mode. LN mode is intended for higher current operation (e.g., >= 10 mA), whereas LP mode is intended for very low current operation (e.g., < 10 mA).

In addition, the DC-DC converter supports an unregulated bypass mode, in which the input voltage is directly shorted to the DC-DC output.

#### 10.3.5.1 Bypass Mode

In bypass mode, the VREGVDD input voltage is directly shorted to the DC-DC converter output through an internal switch. Consult the data sheet for the bypass switch impedance specification.

The Bypass Current Limit limits the maximum current drawn from the input supply in bypass mode. This current limit is enabled by setting the BYPLIMEN bit in the EMU_DCDCCLIMCTRL register, and the limit value may be adjusted between 20 mA and 320 mA using the BYPLIMSEL bitfield in the EMU_DCDCMISCCTRL register. When the difference between the DC-DC output voltage ( $V_{DCDC}$ ) and the DC-DC input voltage (VREGVDD) is large, applications should enable the Bypass Current Limit before enabling Bypass mode. For example, if Bypass mode is enabled with VREGVDD=3.8 V and  $V_{DCDC}$  = 1.8 V with a 4.7  $\mu$ F capacitor, the peak current draw may be quite large as it is limited only by the bypass switch on-resistance, which could result in drooping on the input supply voltage. For smaller input / output voltage differences (e.g., VREGVDD = 2.4 V and  $V_{DCDC}$ =1.8 V), it may not be necessary to enable the Bypass Current Limit at all.

Note that the device will see an additional ~10  $\mu$ A of current draw when both the Bypass Current Limiter and Bypass Mode are enabled. Applications should therefore disable the Bypass Current Limiter (i.e., set BYPLIMEN = 0) after the DVDD voltage has reached the main supply voltage in Bypass Mode.

#### 10.3.5.2 Low Power (LP) Mode

The Low Power (LP) controller operates in a hysteretic mode to keep the output voltage within a defined voltage band. Once the DC-DC output voltage drops below a programmable internal reference, the LP controller generates a pulse train to control the powertrain PFET switch, which charges up the DC-DC output capacitor. When the output voltage is at the programmed upper level, the powertrain PFET is turned off. The output ripple voltage may be quite large (>100 mV) in LP mode.

The LP controller supports load currents up to approximately 10 mA, making it suitable for light loads in EM0 and EM1, as well as EM2, EM3, or EM4 low energy modes.

#### 10.3.5.3 Low Noise (LN) Mode

The Low Noise (LN) controller continuously switches the powertrain NFET and PFET switches to maintain a constant programmed voltage at the DVDD pin. The LN controller supports load current from sub-mA up to 200 mA.

The LN controller switching frequency is programmable using the RCOBAND bitfield in the EMU_DCDCLNFREQCTRL register. See below for recommended RCOBAND settings for each mode.

The DC-DC Low Noise controller operates in one of two modes:

- 1. Continuous Conduction Mode (CCM)
- 2. Discontinuous Conduction Mode (DCM)

## 10.3.5.3.1 Low Noise (LN) Continuous Conduction Mode (CCM)

CCM operation is configured by setting the LNFORCECCM bit in the EMU_DCDCMISCCTRL register. CCM can be used to improve the DC-DC converter's output transient response time to quick load current changes, which minimizes voltage transients on the DC-DC output.

Note that all references to CCM in the documentation actually refer to Forced Continuous Conduction Mode (FCCM) - that is, if the LNFORCECCM bit is set and the output load current is very low, the DC-DC will be forced to operated in CCM. In this case, the current through the inductor may be negative and current may flow back into the battery.

CCM is required for radio or Wireless Gecko systems because, unlike DCM, it allows use of the radio's interference minimization features. In CCM, the recommended DC-DC converter switching frequency is 6.4 MHz (RCOBAND = 4). Note that when the radio's interference minimization features are enabled, RCOBAND = 4 corresponds to a DC-DC converter switching frequency of 7 MHz.

#### 10.3.5.3.2 Low Noise (LN) Discontinuous Conduction Mode (DCM)

To enable DCM, the LNFORCECCM bit in EMU_DCDCMISCCTRL must be cleared before entering LN. Typically, this configuration would occur while the part was in Bypass mode. Once DCM is enabled, the DC-DC should operate in DCM at light load currents. However, as the load current increases, the DC-DC will automatically transition into CCM without software intervention.

The advantage of DCM is improved efficiency for light load currents. However, in DCM the DC-DC has poorer dynamic response to changes in load current, leading to potentially larger changes in the regulated output voltage. In addition, DCM increases the potential RF switching interference, because in DCM the DC-DC switching events are load dependent and can no longer be synchronized with radio operation. For these reasons, DCM is not recommended for radio applications or for non-radio applications that expect large instantaneous load current steps. For example, if the DC-DC is in DCM, firmware may need to increment the core clock frequency in small steps to prevent a large sudden load increase.

In DCM, the recommended DC-DC converter switching frequency is 3 MHz (RCOBAND = 0).

#### 10.3.5.4 DC-to-DC Programming Guidelines

**Note:** Refer to Application Note *AN0948: EFM32 and EFR32 Series 1 Power Configurations and DC-DC* for detailed information on programming the DC-DC. Application Notes can be found on the Silicon Labs website (www.silabs.com/32bit-appnotes) or using the [**Application Notes**] tile in Simplicity Studio.

#### 10.3.6 Analog Peripheral Power Selection

The analog peripherals (e.g., ULFRCO, LFRCO, LFXO, HFRCO, AUXHFRCO, VMON, IDAC, ADC, CSEN) are powered from an internal analog supply domain, VDDX_ANA. VDDX_ANA may be supplied from either the AVDD or DVDD supply pins, depending on the configuration of the ANASW bit in the EMU_PWRCTRL register. Changes to the ANASW setting should be made immediately out of reset (i.e., in the Unconfigured Configuration), before all clocks (with the exception of HFRCO and ULFRCO) are enabled. If the DCDC converter is used and ANASW is set to 1, the switch will not take effect until after the DCDC output voltage has reached its target level. To prevent supply transients, firmware should configure and enable the DCDC, configure ANASW, and then enable clocks.

Once ANASW is configured it should not be changed. Note that the flash is always powered from the AVDD pin, regardless of the state of the ANASW bit.

Table 10.4. Analog Peripheral Power Configuration

ANASW	Analog Peripheral Power Supply Source (VDDX_ANA)	Comments
0 (default)	AVDD pin	This configuration may provide a quieter supply to the analog modules, but is less efficient as AVDD is typically at a higher voltage than DVDD.
1	DVDD pin	This configuration may provide a noisier supply to the analog modules, but is more efficient. However, because the maximum allowable input voltage to many of the analog modules using APORT is limited to MIN(VDDX_ANA,IOVDD), this setting could artificially limit your analog input range.

#### 10.3.7 Digital LDO Power Selection

The digital LDO may be powered from one of two supply pins, depending on the configuration of the REGPWRSEL bit in the EMU_PWRCTRL register. At startup, the digital is powered from the AVDD pin. When powered from AVDD, the LDO current is limited to 20 mA. Out of startup, firmware should configure and enable the DCDC (if desired) and then set REGPWRSEL=1 before increasing the core clock frequency.

Table 10.5. Digital LDO Power Configuration

REGPWRSEL	Digital LDO Power Source	Comments
0 (default)	AVDD pin	Maximum LDO current in this configuration is 20 mA. Firmware should configure REGPWRSEL to 1 after startup.
1	DVDD pin	This configuration supports all core frequencies, and should be used after startup.

#### 10.3.8 IOVDD Connection

The IOVDD supply(s) must be less than or equal to AVDD. IOVDD will typically be connected to either the DC-DC Output (V_{DCDC}) or the main supply.

Because  $V_{DCDC}$  will be unpowered (i.e., floating) at startup, if IOVDD is powered from the DC-DC converter then any circuit attached to IOVDD will not be powered until the DC-DC is configured (or the bypass switch is enabled).

Note: This constraint can have serious and unintended side-effects. For example, if IOVDD=V_{DCDC}:

- 1. It isn't directly possible to program an unprogrammed device on a PCB through the serial wire interface. Programming the device requires IOVDD to be present (i.e., for SWCLK, SWDIO, etc), and IOVDD won't be present until after the part is programmed (i.e., the DC-DC is enabled in firmware to power up V_{DCDC}). It is possible to work around this issue, however, by providing an external supply for V_{DCDC} during programming.
- 2. Some unprogrammed devices are preloaded with a bootloader. The bootloader is expecting to read a logic high on the SWCLK pin to determine if the bootloader should execute. With no valid IOVDD voltage present, the code may incorrectly decide to execute the bootloader, which will cause the system to wait in the bootloader until a reset occurs.

Additionally, upon entry into EM4 Shutoff, the DC-DC converter configuration is reset to its default (Unconfigured) configuration. If  $IOVDD = V_{DCDC}$ , then any circuits attached to IOVDD will remain unpowered until the system is reset to exit EM4 Shutoff, and the DC-DC is configured (or the bypass switch is enabled).

Any application with powering external loads from the DC-DC converter must take into consideration the maximum allowable DC-DC load current. Refer to the data sheet for DC-DC load current specification.

#### 10.3.9 Voltage Scaling

The voltage scaling feature allows for a tradeoff between power and performance. Voltage scaling applies an adjustment to the supply voltage for the on-chip digital logic and memories. For EM0 and EM1 operation, full device performance is supported when the Voltage Scale Level is set to its highest value. The Voltage Scale Level may be set lower when operating the system at slower clock speeds to save power. Voltage scaling does not affect the input or output range for analog peripherals or digital I/O logic levels. For more information about max system frequency supported for different voltage scaling levels. Refer to the CMU chapter and the data sheet specification tables.

Note: Some device sub-systems and operations are only supported at Voltage Scale Level 2.

- Flash write/erase is only supported at Voltage Scale Level 2.
- TRNG operation is only supported at Voltage Scale Level 2.
- HFXO supports only 38-40 MHz crystals and is only supported at Voltage Scale Level 2.
- Radio operation and radio module register access is only supported at Voltage Scale Level 2. When using any other Voltage Scale
  Level access to all radio peripherals is locked out. Thus, firmware may only use Voltage Scale Level 0 during periods when radio
  operations or radio register accesses are not required.

Separate voltage scaling controls are available for the different energy modes. These are as follows:

- EM0/EM1 Voltage Scaling
- EM2/EM3 Voltage Scaling
- · EM4H Voltage Scaling

#### 10.3.9.1 EM0/EM1 Voltage Scaling

In energy modes EM0 and EM1, the user can dynamically scale voltages between Voltage Scale Level 2 and Voltage Scale Level 0 using the EM01VSCALE2 and EM01VSCALE0 bitfields in EMU_CMD register. A lower Voltage Scale Level can be used in conjunction with lower processor frequency to reduce power consumption. Once these commands are issued, hardware begins the process of voltage scaling and when done, the VSCALEDONE interrupt is triggered. Users can also poll VSCALEBUSY in EMU_STATUS which indicates that hardware is busy changing the voltage scale setting when set. VSCALE in EMU_STATUS shows the current voltage the system is in at any time.

#### Note:

- If more than one voltage scaling command is issued in EMU_CMD simultaneously, the lower voltage scaling level has higher priority.
   e.g. priority order: EM01VSCALE0 > EM01VSCALE2.
- The reset value of VSCALE for EM0 and EM1 operation is Voltage Scale Level 2.

When voltage scaling up or down, the user should follow the following sequences in order to ensure proper scaling.

- Voltage Scale Down
  - 1. Decrease system clock frequency to the target frequency
  - 2. Update the wait states of Flash for the target frequency
  - Issue voltage scaling command by setting EM01VSCALE2 or EM01VSCALE0 in EMU_CMD
  - 4. Once Hardware completes voltage scaling up, VSCALEDONE interrupt is set.
- Voltage Scale Up
  - 1. Issue voltage scaling command by setting EM01VSCALE2 or EM01VSCALE0 in EMU_CMD
  - 2. Wait for hardware to complete voltage scaling. When done, VSCALEDONE interrupt is set.
  - 3. Update the wait states of Flash for the target frequency
  - 4. Increase system clock frequency to the target frequency

Multiple voltage scaling commands are allowed to be issued even when the current voltage scaling is not yet completed. In such a case, the current scaling will be aborted and the last command will be executed. VSCALEDONE interrupt will be issued for every voltage scaling command.

**Note:** When a hard reset occurs, VSCALE will be set to the reset value (Voltage Scale Level 2). In most cases, a soft reset will not affect the current VSCALE level. However, when a soft reset is issued in the middle of the voltage scaling process, the minimum voltage scale level indicated by VSCALE or the EMU_CMD which triggered the voltage scale operation will be applied and reflected in VSCALE.

#### 10.3.9.2 EM2/EM3 Voltage Scaling

The EM23VSCALE bitfield in EMU_CTRL allows user to independently setup the voltage scaling value for EM2/EM3 energy mode. The EM23VSCALE in EMU_CTRL should be programmed to a level which is less than or equal to VSCALE in EMU_STATUS. This means that EM2/EM3 voltage scaling is always a voltage scaling down process. If EM23VSCALE level in EMU_CTRL is greater than VSCALE level in EMU_STATUS, the VSCALE level will be implemented in EM2/EM3 instead of EM23VSCALE. Upon EM2/EM3 entry, the system will scale down the voltage to a smaller level between VSCALE or EM23VSCALE.

**Note:** The reset value of EM23VSCALE is Voltage Scale Level 2. Therefore, if user scales EM0/EM1 voltage to Voltage Scale Level 0 (reflected in VSCALE in EMU_STATUS) and enters EM2/EM3, this VSCALE voltage of Voltage Scale Level 0 is maintained in EM2/EM3 as well since this is smaller level between VSCALE and EM23VSCALE.

#### 10.3.9.2.1 EM2/EM3 Voltage Scaling Guidelines

Note that when using EM23VSCALE in EMU_CTRL to scale down EM2/EM3, the scaled down voltage in EM2/EM3 is maintained after waking from EM2/EM3 to EM0/EM1. For example, if VSCALE was at Voltage Scale Level 2 prior to EM2/EM3 entry, and EM23VSCALE was set to Voltage Scale Level 0, the system will scale down to Voltage Scale Level 0 on EM2/EM3 entry. When waking up to EM0/EM1, the system maintains its voltage at Voltage Scale Level 0. Therefore, user must ensure the system clock frequency and Flash wait states are programmed to correct values to support waking up to EM0/EM1 at the lower voltages prior to EM2/EM3 entry.

EM23VSCALEAUTOWSEN bitfield in EMU_CTRL enables hardware to automatically configure the system clock frequency and Flash wait states to support low voltage operation when waking up to EM0/EM1 from EM2/EM3. Therefore, this obviates the need for user to setup the clock frequency and Flash wait states prior to EM2/EM3 entry with EM23VSCALE. When waking up to EM0/EM1, while using EM23VSCALEAUTOWSEN set to 1, the HFRCO will default to its production calibrated 19 MHz frequency.

#### 10.3.9.3 EM4H Voltage Scaling

EM4HVSCALE bitfield in EMU_CTRL allows user to independently setup the voltage scaling levels for EM4H energy mode. The EM4HVSCALE in EMU_CTRL should be programmed to a level which is smaller than or equal to VSCALE level in EMU_STATUS or EM23VSCALE in EMU_CTRL. This means that EM4H voltage scaling is always a voltage scaling down process. If EM4HVSCALE level in EMU_CTRL is greater than level of VSCALE in EMU_STATUS or level of EM23VSCALE in EMU_CTRL, the smaller of VSCALE, EM23VSCALE or EM4HVSCALE levels will be implemented in EM4H.

**Note:** The reset level of EM4HVSCALE is Voltage Scale Level 2. Therefore, if user scales EM0/EM1 voltage to Voltage Scale Level 0 (reflected in VSCALE in EMU_STATUS) and enters EM4H, this VSCALE voltage of Voltage Scale Level 0 is maintained in EM2/EM3 as well since this is minimum of VSCALE and EM23VSCALE.

## 10.3.9.3.1 EM4H Voltage Scaling Guidelines

Note that when using EM4HVSCALE in EMU_CTRL to scale down voltage in EM4H, the scaled down voltage in EM4H is maintained after waking from EM4H to EM0/EM1. For example prior to EM4H entry, if VSCALE was at Voltage Scale Level 2 and EM4HVSCALE was set to Voltage Scale Level 0, the system will scale down to Voltage Scale Level 0 on EM4H entry. When waking up to EM0/EM1, the system maintains its voltage at Voltage Scale Level 0.

#### 10.3.9.4 Voltage Scaling Recommended Use

Refer to the data sheet for the maximum supported system frequencies for different Voltage Scaling Levels. Use of the lowest voltage scaling level is recommended for maximum power savings. For any voltage scaling level, it is recommend to use the highest frequency for performance benefits.

Voltage can then be scaled to higher voltage scale levels only when higher system clock frequency is required by the application for a period of time after which user can dynamically scale the voltage back to lower voltage scale levels to continue saving power.

#### 10.3.10 EM2/EM3 Peripheral Retention Disable

Peripherals that are available in EM2 Deep Sleep or EM3 Stop can optionally be powered down during EM2 Deep Sleep or EM3 Stop. This allows lower energy consumption in these energy modes. However, when powering down, these peripherals are independently reset so the registers lose their configuration values. Therefore, they will have to be reconfigured upon wake-up to EM0 Active if they were previously configured to non reset values.

EMU_EM23PERNORETAINCTRL register can be used to setup unused peripherals for powering down prior to EM2/EM3 entry. Once setup, upon EM2/EM3 entry, all peripherals in the power-down domain will get powered down if all of them are setup to be disabled.

Note: User must ensure that the peripherals being powered down should have their clocks disabled in CMU prior to EM2/EM3 entry.

On waking up from EM2/EM3, EMU_EM23PERNORETAINSTATUS register indicates if the peripherals were powered down by the system and subsequently locked out from register access. Locking out peripherals prevents users from accidentally using peripherals with configurations at their reset state. EMU_EM23PERNORETAINCMD allows user to unlock these peripherals and hence grant access to their registers for updating their configurations.

# 10.3.11 Brown Out Detector (BOD)

The EFR32xG12 Wireless Gecko contains multiple supply brown out detectors (BODs).

#### 10.3.11.1 AVDD BOD

The EFR32xG12 Wireless Gecko has a fast response BOD on AVDD that is always active. This BOD ensures the minimal supply is provided to the AVDD supply (typically also connected to VREGVDD). Once triggered, the BOD will cause the system to reset.

**Note:** In EM4 Hibernate/Shutoff a low power version of the AVDD BOD, called EM4BOD, is available to trigger a reset at level lower than in other energy modes. All other BODs are disabled during EM4 Hibernate/Shutoff

#### 10.3.11.2 DVDD and DECOUPLE BOD

Additional BODs will monitor DVDD and DECOUPLE during EM0 Active through EM3 Stop. This can cause a reset to the internal logic, but will not cause a power-on reset or reset the EMU or RTCC.

#### 10.3.12 Voltage Monitor (VMON)

The EFR32 features an extremely low energy Voltage Monitor (VMON) capable of running down to EM4 Hibernate. Trigger points are preloaded but may be reconfigured.

- AVDD X 2
- DVDD
- IOVDD0

#### Table 10.6. VMON Events

Feature	Condition	AVDD	DVDD	IOVDD
Hysteresis (separate rise and fall triggers)	_	Yes	_	_
Interrupt	Fall or Rise	Yes	Yes	Yes
Wake-Up from EM4 Hibernate	Fall or Rise	Yes	Yes	Yes

The status of the VMON is reflected in the EMU_STATUS register.

The status of the sticky interrupt can be found at EMU_IF. These interrupt flags also serve as the wake-up source of EM4H when the associated RISEWU and FALLWU bits are set. This means that if these flags are set, EM4H entry will result in an immediate wake-up. To prevent this, these must be cleared by software before EM4H entry.

Note that the VMON has offset high hysteresis, specified in the device Data Sheet. For rising edge detection the threshold will be the threshold setting (as described below) + V_{VMON HST}, and for falling edge detection the threshold will simply be the threshold setting.

VMON channels are calibrated at two voltages: 1.86 V and 2.98 V. The calibration results (coarse thresholds and fine thresholds for 1.86 V and 2.98 V) are placed in the VMONCAL registers in the DI page. Using these thresholds it is possible to calculate thresholds for the entire supported VMON VDD range, i.e., 1.62 V to 3.4 V. Using the values given in VMONCAL registers, one can calculate  $T_{1.86}$ ,  $T_{2.98}$ ,  $V_a$  and  $V_b$ .

$$\begin{split} T_{1.86} = & (10 \text{ x VMONCALX_XVDD1V86THRESCOARSE}) + \text{VMONCALX_XVDD1V86THRESFINE}, \\ T_{2.98} = & (10 \text{ x VMONCALX_XVDD2V98THRESCOARSE}) + \text{VMONCALX_XVDD2V98THRESFINE}, \\ V_a = & (1.12) / (T_{2.98} - T_{1.86}), \\ V_b = & 1.86 - (V_a \text{ x T}_{1.86}), \end{split}$$

Figure 10.6. VMON Calibration Equations

Now if it is required to find the coarse and fine thresholds for a certain voltage Y, following equation can be used:

Thres_Y = 
$$(Y - V_b) / V_a$$
,  
 $Y_{calib}$  =  $(Thres_Y \times V_a) + V_b$ ,

Figure 10.7. VMON Threshold Equations

Thres $_{Y}$  should be rounded to the nearest integer. The least significant digit of the rounded Thres $_{Y}$  gives the fine threshold and remaining digits give the coarse threshold for Y. These can now be programmed in the relevant EMU_VMONXVDDCTRL register as the coarse and fine thresholds. It may not be possible to set threshold exactly for Y. In that case the closest possible voltage is used.  $Y_{calib}$  gives the value of this closest possible voltage.

Consider the example where it is required to set the AVDD rise threshold to 2.2 V (so Y=2.2 V). This means that the EMU_VMO-NAVDDCTRL_RISETHRESCOARSE and EMU_VMONAVDDCTRL_RISETHRESFINE need to be programmed. Here are the steps that should be followed:

- Check VMONCAL0 register. It has the VMON AVDD channel calibrated thresholds for 1.86 V and 2.98 V. Lets assume that the following values are present in the associated bitfields:
  - AVDD1V86THRESCOARSE = 3
  - AVDD1V86THRESFINE = 5
  - AVDD2V98THRESCOARSE = 8
  - AVDD2V98THRESFINE = 7

- Using the above numbers and the VMON calibration equations:
  - $T_{1.86} = 35$
  - $T_{2.98} = 87$
  - $V_a = 21.53 \text{ mV}$
  - $V_b = 1.106 V$
- Using the VMON threshold equations (with Y=2.2 V), Thres_Y = 51 (rounded from 50.8) and Y_{calib} = 2.204 V

EMU_VMONAVDDCTRL_RISETHRESCOARSE should be programmed to 5 and EMU_VMONAVDDCTRL_RISETHRESFINE should be programmed to 1 (since Thres $_{\rm Y}$  = 51). With these programmed values, VMON AVDD rise threshold is set for Y_{calib} = 2.204 V, which is the closest programmable threshold.

#### 10.3.13 Powering Off SRAM Blocks

SRAM blocks may be powered off using the EMU_RAMxCTRL RAMPOWERDOWN fields. Selected blocks are powered down in order from the highest to lowest address in each bank. The lowest SRAM block in RAM0 cannot be powered off and will always remain powered on for proper system functionality. The stack must be located in retained memory. Refer to the EMU_RAMxCTRL register descriptions for power configuration options and the associated address ranges.

#### 10.3.14 Temperature Sensor

EMU provides low energy periodic temperature measurement. A temperature measurement is taken every 250 ms, with the 8-bit result stored in EMU->TEMP register.

Note: The EMU temperature sensor is always running (except in EM4 Shutoff) and is independent from the ADC temperature sensor.

The EMU provides the following features around temperature changes

- · Wake-Up from EM4 Hibernate on Temperature Change
- · Interrupt from High Level Trip
- · Interrupt from Low Level Trip

During production test, the EMU temperature sensor for each device is calibrated at room temperature, with the corresponding calibration temperature and reading stored off in the DI page as follows:

- DEVINFO->CAL.TEMP: This bitfield contains the temperature in degrees C at calibration
- DEVINFO->EMUTEMP: This register contains the EMU->TEMP reading at the calibration temperature stored in DEVINFO->CAL.TEMP

The current calibrated EMU temperature sensor result from EMU->TEMP may be converted to degrees C using the following equation:

#### Figure 10.8. Temperature Calculation

TEMPCO_{EMxx} is a temperature coefficient that varies based on the energy mode at the time of the EMU temperature sensor reading:

- TEMPCO_{EM01} = 0.278 + (DEVINFO->EMUTEMP) / 100
- TEMPCO_{EM234} = 0.268 + (DEVINFO->EMUTEMP) / 100

For maximum accuracy when using the high/low level temperature interrupts, firmware should ensure that TEMPCO_{EM234} is used to set the temperature thresholds in EMU->TEMPLIMITS before entering EM2/3/4. Similarly, when exiting EM2/3/4, the temperature thresholds should be updated using TEMPCO_{EM01}.

Note that an increasing reading in EMU->TEMP corresponds to a decreasing temperature, and vice-versa. If enabled, the TEMPHIGH High Level Limit in EMU-> TEMPLIMITS causes an interrupt flag on a increasing EMU->TEMP reading (i.e., decreasing temperature). Similarly, the TEMPLOW Low Level Limit causes a interrupt flag on a decreasing EMU->TEMP reading (i.e., increasing temperature).

The EMU temperature sensor accuracy is approximately ±10°C over most of the useable temperature range, but may be +15°C at higher temperatures. Accordingly, any use of the EMU temperature sensor should include margin to account for that accuracy.

#### 10.3.15 Registers latched in EM4

The following registers will be latched when entering EM4. After wake-up from EM4, these registers will be reset and require reprogramming prior to writing the EMU_CMD_EM4UNLATCH command.

- CMU LFRCOCTRL
- CMU LFXOCTRL
- CMU_LFECLKSEL
- CMU_LFECLKEN0
- CMU_LFEPRESC0

#### 10.3.16 Register Resets

Each EMU register requires retaining state in various energy modes and power transitions and will consequently need to be reset with a different condition. The following reset conditions will apply to the appropriate set of registers as marked in the Register Description table.

- · Reset with POR or Hard Pin Reset
- · Reset with POR, Hard Pin Reset, or any BOD reset
- Reset with SYSEXTENDEDRESETn
- · Reset with FULLRESETn (default)

If a register field is not marked with a specific reset condition then it is assumed to be reset with FULLRESETn.

## 10.4 Register Map

The offset register address is relative to the registers base address.

Offset	Name	Туре	Description

Bit	Name	Reset	Access	Description
31:7	Reserved	To ensure co	mpatibility	with future devices, always write bits to 0. More information in 1.2 Conven-
6	EM01VSCALE2	0	W1	EM01 Voltage Scale Command to Scale to Voltage Scale Level 2
	Start EM01 voltage s 2 followed by an VS			vel 2. Write to this register will trigger voltage scaling to Voltage Scale Level
5	Reserved	To ensure co	mpatibility	with future devices, always write bits to 0. More information in 1.2 Conven-
4	EM01VSCALE0	0	W1	EM01 Voltage Scale Command to Scale to Voltage Scale Level 0
	Start EM01 voltage s 0 followed by an VS			vel 0. Write to this register will trigger voltage scaling to Voltage Scale Level
3:1	Reserved	To ensure co	ompatibility	with future devices, always write bits to 0. More information in 1.2 Conven-
0	EM4UNLATCH	0	W1	EM4 Unlatch
	wakeup, these regist tion from EM4 to EM	ers will be reset 10, the unlatch o	and can hacommand s	latched in order to maintain constant functionality throughout EM4. Upon ave contradictory values to the latched values. To ensure a seamless transihould be given after properly reconfiguring these latched registers. The uncondition but is only needed after EM4 wakeup.

## 10.5.6 EMU_EM4CTRL - EM4 Control Register

Name   Reset   Access   Description	RW 0
Reset	RW 0
Name  Name  Reset Access Description  Reset Access Description	RW .
Name   EM4   OPE   PROPERTY   PRO	
Bit Name Reset Access Description	EM4STATE
*	
31:18 Reserved To ensure compatibility with future devices, always write bits to 0. More information in 1.2 Convitions	∍n-
17:16 EM4ENTRY 0x0 W1 Energy Mode 4 Entry	
This register is used to enter the Energy Mode 4 sequence. Writing the sequence 2,3,2,3,2,3,2,3,2 will enter the part in Energy Mode 4.	0
15:6 Reserved To ensure compatibility with future devices, always write bits to 0. More information in 1.2 Convitions	∍n-
5:4 EM4IORETMODE 0x0 RW <b>EM4 IO Retention Disable</b>	
Determine when IO retention will be applied and removed.	
Value Mode Description	
0 DISABLE No Retention: Pads enter reset state when entering EM4	
1 EM4EXIT Retention through EM4: Pads enter reset state when exiting EM4	
2 SWUNLATCH Retention through EM4 and Wakeup: software writes UNLATCH register to remove retention	i <del>-</del>
3 RETAINULFRCO 0 RW ULFRCO Retain During EM4S	
Retain the ULFRCO upon EM4S entry. If set to 1, an already running ULFRCO will be retained in its running state in El ULFRCO will always be retained if EM4STATE is in EM4H.	<i>1</i> 4.
2 RETAINLFXO 0 RW LFXO Retain During EM4	
Retain the LFXO upon EM4(SH/H) entry. If set to 1, an already running LFXO will be retained in its running state in EM	1.
1 RETAINLFRCO 0 RW LFRCO Retain During EM4	
Retain the LFRCO upon EM4(S/H) entry. If set to 1, an already running LFRCO will be retained in its running state in E	VI4.
0 EM4STATE 0 RW Energy Mode 4 State	
When set, the system will enter Hibernate state (EM4H) when entering EM4. In EM4H, the regulator will be on in redu mode allowing for RTCC. Otherwise, when entering in EM4, the regulator will be disabled allowing for lowest power mc Shutoff state (EM4S). Only reset with POR or Hard Pin Reset	
Value Mode Description	
0 EM4S EM4S Shutoff state

Bit	Name	Reset	Access	Description
31:8	Reserved	To ensure o	compatibility	with future devices, always write bits to 0. More information in 1.2 Conven-
7:0	TEMP	0xXX	R	Temperature Measurement

Value of last periodic temperature measurement. Value is asynchronously updated. Value is stable for 250 ms after a temperature-based interrupt (TEMPHIGH, TEMPLOW, or TEMP) and can be read with a single read operation. If register is read not in response to a temperature-based interrupt, multiple readings should be taken until two consecutive values are the same.

## 11. CMU - Clock Management Unit

#### **Quick Facts**

#### What?

The CMU controls oscillators and clocks. EFR32xG12 Wireless Gecko supports 6 different oscillators with minimized power consumption and short start-up time. The CMU has HW support for calibration of RC oscillators.

#### Why?

Oscillators and clocks contribute significantly to the power consumption of an MCU. Low power oscillators combined with a flexible clock control scheme make it possible to minimize the energy consumption in any given application.

#### How?

The CMU can configure different clock sources, enable/disable clocks to peripherals on an individual basis and set the prescaler for the different clocks. The short oscillator start-up times makes duty-cycling between active mode and the different low energy modes (EM2 Deep Sleep, EM3 Stop, and EM4 Hibernate/Shutoff) very efficient. The calibration feature ensures high accuracy RC oscillators. Several interrupts are available to avoid CPU polling of flags.

## 11.1 Introduction

The Clock Management Unit (CMU) is responsible for controlling the oscillators and clocks in the EFR32xG12 Wireless Gecko. The CMU provides the capability to turn on and off the clock on an individual basis to all peripheral modules in addition to enable/disable and configure the available oscillators. The high degree of flexibility enables software to minimize energy consumption in any specific application by not wasting power on peripherals and oscillators that do not need to be active.

#### 11.2 Features

- · Multiple clock sources available:
  - 38 MHz 40 MHz High Frequency Crystal Oscillator (HFXO)
  - 1 MHz 38 MHz High Frequency RC Oscillator (HFRCO)
  - 1 MHz 38 MHz Auxiliary High Frequency RC Oscillator (AUXHFRCO)
  - 32768 Hz Low Frequency Crystal Oscillator (LFXO)
  - 32768 Hz Low Frequency RC Oscillator (LFRCO)
  - 1000 Hz Ultra Low Frequency RC Oscillator (ULFRCO)
- · All oscillator sources are low power.
- Fast start-up times.
- Separate prescalers for High Frequency Core Clocks (HFCORECLK), Radio Clocks (HFRADIOCLK), and Peripheral Clocks (HFPERCLK).
- Individual clock prescaler selection for each Low Energy Peripheral.
- · Clock gating on an individual basis to core modules and all peripherals.
- · Selectable clock output to external pins and/or PRS.
- Wakeup interrupt for LFRCO or LFXO ready allows entry into EM2 Deep Sleep while waiting for low-frequency oscillator startup. This avoids the need for software polling and saves power during oscillator startup.
- Auxiliary 1 MHz 38 MHz RC oscillator (AUXHFRCO), which is asynchronous to the HFSRCCLK system clock, can be selected for ADC operation, LESENSE timing and debug trace.

## 11.3 Functional Description

An overview of the high frequency portion of the CMU is shown in Figure 11.1 CMU Overview - High Frequency Portion on page 301. An overview of the low frequency portion is shown in Figure 11.2 CMU Overview - Low Frequency Portion on page 302. These figures show the CMU for the largest device in the EFR32 family. Refer to the Configuration Summary in the device data sheet to see which core, radio, and peripheral modules, and therefore clock connections, are present in a specific device.

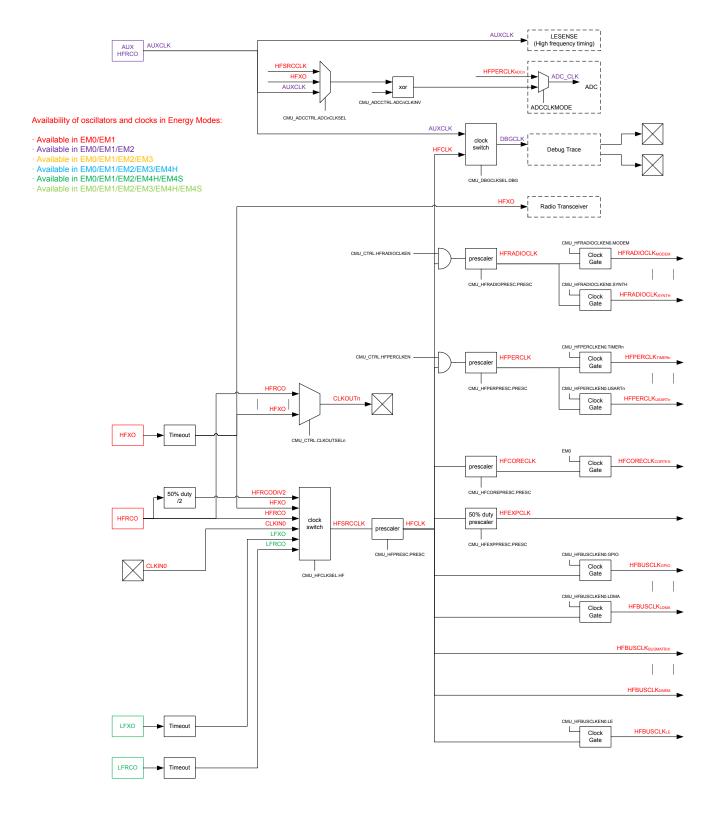

Figure 11.1. CMU Overview - High Frequency Portion

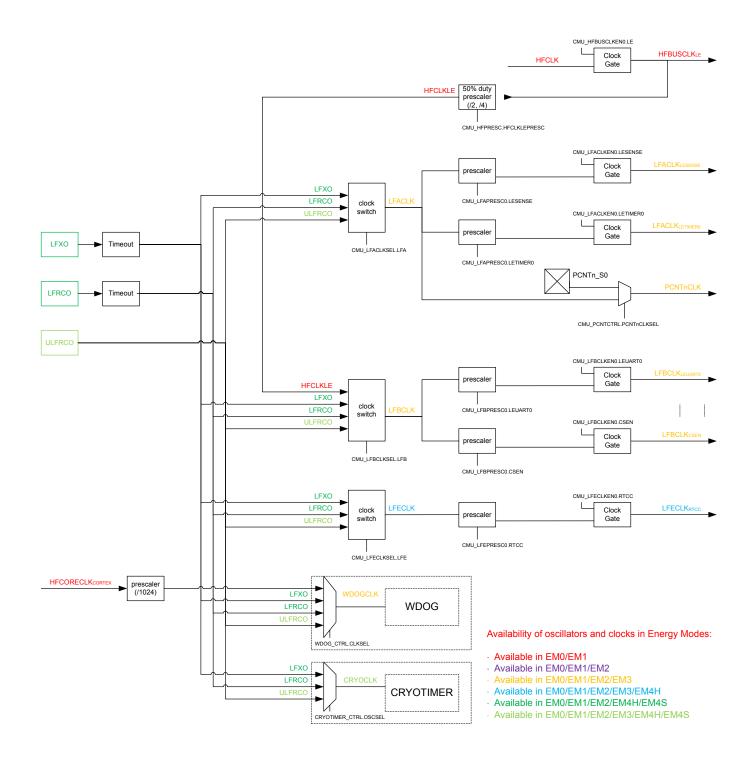

Figure 11.2. CMU Overview - Low Frequency Portion

# 11.3.1 System Clocks

Available system clock sources are detailed in the following sections.

#### 11.3.1.1 HFCLK - High Frequency Clock

HFSRCCLK is the selected High Frequency Source Clock. HFCLK is an optionally prescaled version of HFSRCCLK. The HFSRCCLK, and therefore HFCLK, can be driven by a high-frequency oscillator, such as HFRCO or HFXO, or one of the low-frequency oscillators (LFRCO or LFXO). Additionally, HFSRCCLK can also be driven from a pin (CLKINO) described in 11.3.6 Clock Input From a Pin. By default the HFRCO is selected. In most applications, one of the high frequency oscillators will be the preferred choice. To change the selected clock source, write to the HF bitfield in CMU_HFCLKSEL. The high frequency clock source can also be changed automatically by hardware as explained in 11.3.2.4.1 Automatic HFXO Start. The currently selected source for HFSRCCLK and HFCLK can be read from CMU_HFCLKSTATUS. The HFSRCCLK is running in EM0 Active and EM1 Sleep and is automatically stopped in EM2 Deep Sleep. During Voltage Scaling (see 10.3.9 Voltage Scaling), if a fixed frequency oscillator source (i.e. HFXO or CLKINO) exceeds the maximum system frequency supported, it must be disabled or not selected. Likewise, an adjustable oscillator source (i.e. HFRCO or AUXHFRCO) must be configured to not exceed the maximum system frequency supported before voltage scaling is applied.

**Note:** If a low frequency clock (i.e. LFRCO or LFXO) is selected as source clock for HFSRCCLK via the HF bitfield in CMU_HFCLKSEL, then no register reads should be performed from Low Energy Peripherals for registers which can change value every clock cycle (e.g., a counter register). In addition to the peripherals on LFACLK, LFBCLK and LFECLK, this restriction applies in general to any low frequency peripheral, which is not directly or indirectly clocked from HFSRCCLK (e.g., WDOGn).

HFCLK can optionally be prescaled by setting PRESC in CMU_HFPRESC to a non-zero value. This prescales HFCLK to all high frequency components and is typically used to save energy in applications where the system is not required to run at the highest frequency. The prescaler setting can be changed dynamically and the new setting takes effect immediately. HFCLK is used by the CMU and drives the prescalers that generate HFCORECLK, HFRADIOCLK and HFPERCLK allowing for flexible clock prescaling. The HFBUSCLK, used in for example the bus and memory system, is equal to HFCLK.

The HFXO clock is fed directly to the Radio Transceiver. The clock received by the Radio Transceiver is therefore not affected by the selected clock source for HFSRCCLK nor by any clock prescaler.

## 11.3.1.2 HFCORECLK - High Frequency Core Clock

HFCORECLK is a prescaled version of HFCLK. This clock drives the Core Modules, which consists of the CPU and modules that are tightly coupled to the CPU (e.g., the cache). The prescale factor for prescaling HFCLK into HFCORECLK is set using the CMU_HFCOREPRESC register. The setting can be changed dynamically and the new setting takes effect immediately.

**Note:** If HFPERCLK or HFRADIOCLK runs faster than HFCORECLK, the number of clock cycles for each bus-access to (radio) peripheral modules will increase with the ratio between the clocks. Refer to 4.2.5 Bus Matrix for more details.

#### 11.3.1.3 HFBUSCLK - High Frequency Bus Clock

HFBUSCLK is equal to HFCLK. This clock drives the Bus and Memory System. HFBUSCLK is also used to drive the bus interface to the Low Energy Peripherals as described further in 11.3.1.7 LFACLK - Low Frequency a Clock, 11.3.1.8 LFBCLK - Low Frequency B Clock and 11.3.1.9 LFECLK - Low Frequency E Clock. Some of the modules that are driven by this clock can be clock gated completely when not in use. This is done by clearing the clock enable bit for the specific module in CMU_HFBUSCLKEN0. The frequency of HFBUSCLK is equal to the frequency of HFCLK and can therefore only be prescaled by using the PRESC bitfield in CMU_HFPRESC.

## 11.3.1.4 HFPERCLK - High Frequency Peripheral Clock

Like HFCORECLK, HFPERCLK is a prescaled version of HFCLK. This clock drives the High-Frequency Peripherals. All the peripherals that are driven by this clock can be clock gated individually when not in use. This is done by clearing the clock enable bit for the specific peripheral in CMU_HFPERCLKEN0. All high frequency peripheral clocks can be universally and simultaneously gated by clearing the HFPERCLKEN bit in the CMU_CTRL register. The prescale factor for prescaling HFCLK into HFPERCLK is set using the CMU_HFPERPRESC register. The setting can be changed dynamically and the new setting takes effect immediately.

**Note:** If HFPERCLK runs faster than HFCORECLK, the number of clock cycles for each bus-access to peripheral modules will increase with the ratio between the clocks. For example, if a bus-access normally takes three cycles, it will take 9 cycles of HFCORECLK if HFPERCLK runs three times as fast as HFCORECLK.

#### 11.3.1.5 HFRADIOCLK - High Frequency Radio Clock

HFRADIOCLK is a prescaled version of HFCLK which drives the High-Frequency Radio Peripherals. All the radio peripherals that are driven by this clock can be clock gated completely when not in use. This is done by clearing the clock enable bit for the specific peripheral in CMU_HFRADIOCLKENO. The radio peripherals can also be gated simultaneously by clearing the HFRADIOCLKEN bit in the CMU_CTRL register. The prescale factor for prescaling HFCLK into HFRADIOCLK is set using the CMU_HFRADIOPRESC register. The setting can be changed dynamically and the new setting takes effect immediately.

**Note:** If HFRADIOCLK runs faster than HFCORECLK, the number of clock cycles for each bus-access to radio peripheral modules will increase with the ratio between the clocks. E.g. if a bus-access normally takes three cycles, it will take 9 cycles if HFRADIOCLK runs three times as fast as the HFCORECLK.

#### 11.3.1.6 ADCnCLK - ADC Core Clock

ADCnCLK is a selectable core clock for ADCn. There are three selectable sources for ADCnCLK: HFSRCCLK, HFXO and AUXHFR-CO. In addition, the ADCnCLK can be disabled, which is the default setting. The selection is configured using the ADCnCLKSEL field in CMU_ADCCTRL. The ADCnCLKINV bit in CMU_ADCCTRL can be used to invert ADCnCLK. The ADCnCLKDIV bitfield in CMU_ADCCTRL can be used to prescale ADCnCLK. The bus interface of ADCn is clocked with HFBUSCLK.

## 11.3.1.7 LFACLK - Low Frequency a Clock

LFACLK is the selected clock for the Low Energy A Peripherals. There are several selectable sources for LFACLK: LFRCO, LFXO and ULFRCO. In addition, the LFACLK can be disabled, which is the default setting. The selection is configured using the LFA field in CMU LFACLKSEL.

The bus interface to the Low Energy A Peripherals is clocked by HFBUSCLK_{LE} and this clock therefore needs to be enabled when programming a Low Energy (LE) peripheral.

Each Low Energy Peripheral that is clocked by LFACLK has its own prescaler setting and enable bit. The prescaler settings are configured using CMU LFAPRESC0 and the clock enable bits can be found in CMU LFACLKEN0.

When operating in oversampling mode, the pulse counters are clocked by LFACLK. This is configured for each pulse counter (n) individually by setting PCNTnCLKSEL in CMU PCNTCTRL.

## 11.3.1.8 LFBCLK - Low Frequency B Clock

LFBCLK is the selected clock for the Low Energy B Peripherals. There are several selectable sources for LFBCLK: LFRCO, LFXO, HFCLKLE and ULFRCO. In addition, the LFBCLK can be disabled, which is the default setting. The selection is configured using the LFB field in CMU_LFBCLKSEL. The HFCLKLE setting allows the Low Energy B Peripherals to be used as high-frequency peripherals.

The bus interface to the Low Energy B Peripherals is clocked by HFBUSCLK_{LE} and this clock therefore needs to be enabled when programming a LE peripheral.

Note: If HFCLKLE is selected as LFBCLK, the clock will stop in EM2 Deep Sleep and EM3 Stop.

Each Low Energy Peripheral that is clocked by LFBCLK has its own prescaler setting and enable bit. The prescaler settings are configured using CMU_LFBPRESC0 and the clock enable bits can be found in CMU_LFBCLKEN0.

#### 11.3.1.9 LFECLK - Low Frequency E Clock

LFECLK is the selected clock for the Low Energy E Peripherals. There are several selectable sources for LFECLK: LFRCO, LFXO and ULFRCO. In addition, the LFECLK can be disabled, which is the default setting. The selection is configured using the LFE field in CMU_LFECLKSEL.

The bus interface to the Low Energy E Peripherals is clocked by HFBUSCLK_{LE} and this clock therefore needs to be enabled when programming a LE peripheral.

Note: LFECLK is in a different power domain than LFACLK and LFBCLK, which makes it available all the way down to EM4 Hibernate.

Each Low Energy Peripheral that is clocked by LFECLK has its own prescaler setting and enable bit. The prescaler settings are configured using CMU LFEPRESC0 and the clock enable bits can be found in CMU LFECLKEN0.

#### 11.3.1.10 PCNTnCLK - Pulse Counter N Clock

Each available pulse counter is driven by its own clock, PCNTnCLK where n is the pulse counter instance number. Each pulse counter can be configured to use an external pin (PCNTn_S0) or LFACLK as PCNTnCLK.

## 11.3.1.11 WDOGnCLK - Watchdog Timer Clock

The Watchdog Timer (WDOGn) can be configured to use one of many different clock sources. Refer to CLKSEL field in WDOGn_CTRL for a complete list.

#### 11.3.1.12 CRYOCLK - CRYOTIMER Clock

The CRYOTIMER clock can be configured to use one of many different clock sources. Refer to OSCSEL field in CRYOTIMER_CTRL for a complete list. The CRYOTIMER can also run in EM4 Hibernate/Shutoff provided that its selected clock is kept enabled as configured in EMU EM4CTRL.

#### 11.3.1.13 AUXCLK - Auxiliary Clock

AUXCLK is a 1 MHz - 38 MHz clock driven by a separate RC oscillator, the AUXHFRCO. This clock can be used for ADC operation LESENSE operation. When the AUXHFRCO is selected as the ADCn clock via the ADCnCLKSEL bitfield in the CMU_ADCCTRL register, or if needed by LESENSE, this clock will become active automatically when needed. Even if the AUXHFRCO has not been enabled explicitly by software, the ADC or LESENSE can automatically start and stop it. The AUXHFRCO is explicitly enabled by writing a 1 to AUXHFRCOEN in CMU_OSCENCMD. This explicit enabling is required when selecting the AUXCLK for SWO operation.

#### 11.3.1.14 Debug Trace Clock

The CMU selects the clock used for debug trace via the DBGCLKSEL register. The user can useAUXHFRCO or the HFCLK. The selected debug trace clock will be used to run the Cortex-M4 trace logic.

Note: When using AUXHFRCO as the debug trace clock, it must be stopped before entering EM2 or EM3.

#### 11.3.2 Oscillators

Control of the various oscillators available in the device is detailed in the following sections.

# 11.3.2.1 Enabling and Disabling

The different oscillators can typically be enabled and disabled via both hardware and software mechanisms. Enabling via software is done by setting the corresponding enable bit in the CMU_OSCENCMD register. Disabling via software is done by setting the corresponding disable bit in CMU_OSCENCMD. Enabling via hardware can be performed by various peripherals and varies per oscillator. Disabling via hardware is typically performed on entry of low energy modes. The enable and disable mechanisms for each of the oscillators are summarized in Table 11.1 Software Based and Hardware Based Enabling and Disabling of Oscillators on page 306 and described in more detail below.

Table 11.1. Software Based and Hardware Based Enabling and Disabling of Oscillators

Oscillator	SW Enable	SW Disable	HW Enable	HW Disable
ULFRCO	-	-	Enabled when in EM0/EM1/EM2/EM3/ EM4H.	EM4S entry depending on configuration in EMU_EM4CTRL.
LFRCO	Via LFRCOEN in CMU_OSCENCMD.	Via LFRCODIS in CMU_OSCENCMD.	Via WDOGn if it is configured to use LFRCO as its clock source via the CLKSEL bitfield in WDOGn_CTRL while SWOSCBLOCK is set.	EM3 entry. EM4 entry depending on configuration in EMU_EM4CTRL.
LFXO	Via LFXOEN in CMU_OSCENCMD.	Via LFXODIS in CMU_OSCENCMD.	Via WDOGn if it is configured to use LFXO as its clock source via the CLKSEL bitfield in WDOGn_CTRL while SWOSCBLOCK is set.	EM3 entry. EM4 entry depending on configuration in EMU_EM4CTRL.
HFRCO	Via HFRCOEN in CMU_OSCENCMD.	Via HFRCODIS in CMU_OSCENCMD.	Reset exit. EM2/EM3 exit. Automatic control by LEUART RX/TX DMA wake-up as configured in LEUARTn_CTRL.	EM2/EM3/EM4 entry. Automatic control by LEUART RX/TX DMA wake-up as configured in LEUARTn_CTRL. Automatic start and selection of HFXO causes HFRCO disable.
AUXHFRCO	Via AUXHFRCOEN in CMU_OSCENCMD.	Via AUXHFRCODIS in CMU_OSCENCMD.	Automatic control by ADC and LESENSE.	EM2/EM3/EM4 entry. Automatic control by ADC and LESENSE even in EM2/EM3.
HFXO	Via HFXOEN in CMU_OSCENCMD.	Via HFXODIS in CMU_OSCENCMD.	Automatic start by Radio Controller (RAC) or EM0/EM1 entry as con- figured in CMU_HFXOCTRL.	EM2/EM3/EM4 entry.

#### 11.3.2.1.1 LFRCO and LFXO

The LFXO and LFRCO can be enabled and disabled by software via the CMU_OSCENCMD register. WDOGn can be configured to force the LFXO or LFRCO to become (and remain) enabled when such an oscillator is selected as its clock source via the CLKSEL bitfield in the WDOGn_CTRL register while SWOSCBLOCK is set. In that case LFXODIS and LFRCODIS commands are blocked. They are automatically disabled when entering EM3. Upon EM4 entry they are default turned off, but they can optionally be retained depending on the EMU_EM4CTRL configuration. Retaining of the LFXO or LFRCO in EM4 is needed if such an oscillator is required by a specific peripheral in EM4. Retaining can also be used to guarantee guick oscillator availability after EM4 exit.

The oscillators should never be retained in case they are off before entering EM4. The following are the valid ways of using the LFXO/LFRCO retention mechanism:

- Turn on LFXO/LFRCO always (even in EM4):
  - 1. POR
  - 2. Enable LFXO/LFRCO
  - 3. Enable RETAINLFXO/RETAINLFRCO
  - 4. EM4 entry
  - 5. LFXO/LFRCO are retained and remain running in EM4
  - 6. EM4 wakeup
  - 7. Enable LFXO/LFRCO
  - 8. Set EM4UNLATCH in EMU CMD
- Turn off LFXO/LFRCO in EM4:
  - 1. POR
  - 2. Disable RETAINLFXO/RETAINLFRCO (default)
  - 3. Enable LFXO/LFRCO
  - 4. EM4 entry
  - 5. LFXO/LFRCO are off in EM4
  - 6. EM4 wakeup
  - 7. Enable LFXO/LFRCO
  - 8. Set EM4UNLATCH in EMU CMD
- · Turn on LFXO/LFRCO after EM4 exit:
  - 1. POR
  - 2. Disable RETAINLFXO/RETAINLFRCO (default)
  - 3. Enable LFXO/LFRCO
  - 4. EM4 entry
  - 5. LFXO/LFRCO are off in EM4
  - 6. EM4 wakeup
  - 7. Enable LFXO/LFRCO
  - 8. Set EM4UNLATCH in EMU_CMD
  - 9. Enable RETAINLFXO/RETAINLFRCO

In summary RETAINLFXO/RETAINLFRCO should either be changed once after POR and kept static, or they can be changed on-the-fly only after asserting EM4UNLATCH.

#### Note:

- In order to support usage of LFRCO and LFXO in EM4, their settings are automatically latched upon EM4 entry. These settings
  remain latched upon wake-up from EM4 to EM0 although the related registers (CMU_LFRCOCTRL, CMU_LFXOCTRL,
  CMU_LFECLKSEL, CMU_LFECLKEN0 and CMU_LEEPRESC0) will have been reset. The registers can be rewritten by software,
  but they will only affect the LFRCO and LFXO after unlatching their settings by setting EM4UNLATCH in the EMU_CMD register.
- Turning off the LFRCO and LFXO upon EM4 Hibernate/Shutoff entry is most easily done by using the RETAINLFRCO and RETAINLFXO bitfields from the EMU_EM4CTRL register, which are default such that the LFRCO and LFXO are turned off automatically upon EM4 Hibernate/Shutoff entry. Alternatively the LFRCO and LFXO can be disabled via the CMU_OSCENCMD register, in which case software should wait for the oscillators to be properly disabled before executing the EM4 Hibernate/Shutoff entry routine.

After enabling the LFRCO (or LFXO), it should not be disabled before it has been signaled to be ready. Similarly, after disabling the LFRCO (or LFXO), it should not be re-enabled before it has been signaled to be non-ready. Before entering EM4, software should check that the LFRCO (or LFXO) is signaled to be ready before allowing or initiating the EM4 entry if that oscillator is required in EM4. Also, to guarantee latching the latest settings, no control write should be ongoing upon EM4 entry as can be checked via the CMU SYNCBUSY register. Typical enable and disable sequences are as follows:

```
CMU->OSCENCMD = CMU_OSCENCMD_LFRCOEN;
while ((CMU->STATUS & CMU_STATUS_LFRCORDY) != CMU_STATUS_LFRCORDY);

CMU->OSCENCMD = CMU_OSCENCMD_LFRCODIS;
while ((CMU->STATUS & CMU_STATUS_LFRCORDY) == CMU_STATUS_LFRCORDY);
```

When the LFXO is disabled, the interface to the LFXTAL_N and LFXTAL_P pins are set in a high-Z state. The XTAL oscillations will not stop immediately when LFXO is disabled, but typically die out gradually over some 100 ms. If the LFXO is enabled before XTAL oscillations have had time to reach zero amplitude, startup time can be significantly shorter.

**Note:** The LFRCORDY and LFXORDY interrupts can be used to wake up the system from EM2 Deep Sleep. In this way busy waiting for the LFRCO or LFXO to become ready can be avoided by going into EM2 after enabling these oscillators and sleeping until the interrupt causes a wakeup.

#### 11.3.2.1.2 ULFRCO

The ULFRCO is automatically enabled in EM0, EM1, EM2, EM3, and EM4H and cannot be controlled via CMU_OSCENCMD. It is automatically disabled upon entering EM4S unless prevented by the configuration in EMU_EM4CTRL.

#### 11.3.2.1.3 HFRCO

The HFRCO can be enabled and disabled by software via the CMU_OSCENCMD register. The HFRCO is disabled automatically when entering EM2, EM3, or EM4. Further hardware based enabling and disabling can be performed by the LEUART when using automatic RX/TX DMA wakeup as controlled by the RXDMAWU and TXDMAWU bits in the LEUARTn_CTRL register. An automatic start and selection of the HFXO will lead to an automatic HFRCO disabling.

The supported HFRCO frequency range is from 1 MHz to 38 MHz. The default HFRCO frequency is 19 MHz

#### 11.3.2.1.4 HFXO

The HFXO can be enabled and disabled by software via the CMU_OSCENCMD register. The HFXO is disabled automatically when entering EM2, EM3, or EM4. Hardware based HFXO enabling can be initiated by various peripherals as configured via the AUTOSTARTRDYSELRAC, AUTOSTARTEM0EM1, and AUTOSTARTSELEM0EM1 bits in the CMU_HFXOCTRL register. The interaction between hardware based and software based control of the HFXO is further explained in 11.3.2.4.1 Automatic HFXO Start.

The supported HFXO frequency range is from 38 MHz to 40 MHz.

After enabling the HFXO, it should not be disabled before it has been signaled to be enabled. Similarly, after disabling the HFXO it should not be re-enabled before it has been signaled to be non-enabled. Typical enable and disable sequences are as follows:

```
CMU->OSCENCMD = CMU_OSCENCMD_HFXOEN;
while ((CMU->STATUS & CMU_STATUS_HFXOENS) != CMU_STATUS_HFXOENS);

CMU->OSCENCMD = CMU_OSCENCMD_HFXODIS;
while ((CMU->STATUS & CMU_STATUS_HFXOENS) == CMU_STATUS_HFXOENS);
```

#### 11.3.2.1.5 AUXHFRCO

The AUXHFRCO can be enabled and disabled by software via the CMU_OSCENCMD register. The AUXHFRCO is disabled automatically when entering EM2, EM3, or EM4. Hardware based AUXHFRCO enabling and disabling is however performed by the ADC module when AUXCLK is selected for its operation and by the LESENSE module making it available even when being in EM2/EM3.

The supported AUXHFRCO frequency range is from 1 MHz to 38 MHz. The default AUXHFRCO frequency is 19 MHz

After enabling the AUXHFRCO, it should not be disabled before it has been signaled to be enabled. Similarly, after disabling the AUXHFRCO, it should not be re-enabled before it has been signaled to be non-enabled. Typical enable and disable sequences are as follows:

```
CMU->OSCENCMD = CMU_OSCENCMD_AUXHFRCOEN;
while ((CMU->STATUS & CMU_STATUS_AUXHFRCOENS) != CMU_STATUS_AUXHFRCOENS);

CMU->OSCENCMD = CMU_OSCENCMD_AUXHFRCODIS;
while ((CMU->STATUS & CMU_STATUS_AUXHFRCOENS) == CMU_STATUS_AUXHFRCOENS);
```

**Note:** When using AUXHFRCO as the debug trace clock (as selected in CMU_DBGCLKSEL), it must be stopped before entering EM2 or EM3.

#### 11.3.2.2 Oscillator Start-up Time and Time-out

The start-up time differs per oscillator and the usage of an oscillator clock can further be delayed by a time-out. The LFRCO, LFXO and the HFXO have a configurable time-out which is set by software in the (various) TIMEOUT bitfields of the CMU_LFRCOCTRL, CMU_LFXOCTRL and CMU_HFXOTIMEOUTCTRL registers respectively. The time-out delays the assertion of the READY signal for LFRCO, LFXO and HFXO and should allow for enough time for the oscillator to stabilize. The time-out can be optimized for the chosen crystal (for LFXO and HFXO) used in the application. In case LFRCO and/or LFXO has been retained throughout EM4 Hibernate/Shutoff, such retained oscillators can be quickly restarted for use as LFACLK, LFBCLK or LFECLK by using the minimum TIMEOUT settings for them. For the other RC oscillators (HFRCO, AUXHFRCO, and ULFRCO), the start-up time is known and a fixed time-out is used.

There are individual bits in the CMU STATUS register for each oscillator indicating the status of the oscillator:

- · ENABLED Indicates that the oscillator is enabled
- · READY Start-up time including time-out is exceeded

These status bits are located in the CMU STATUS register.

Additionaly, the HFXO has a second time-out counter which can be used to achieve deterministic start-up time based on timing from the LFXO, ULFRCO, or LFRCO. This second counter runs off LFECLK and can be programmed via the LFTIMEOUT bitfield in the CMU_HFXOCTRL register. It can be used when waking up from EM2 when either ULFRCO, LFRCO or LFXO is already running and stable. In this case the HFXO ready assertion can be delayed with the number of LFECLK cycles as programmed in LFTIMEOUT. The HFXO ready signal is asserted when both the TIMEOUT counter (configured via the CMU_HFXOTIMEOUTCTRL register) and the LFTIMEOUT counter (configured via CMU_HFXOCTRL register) have timed out as shown in Figure 11.3 CMU Deterministic HFXO startup using LFTIMEOUT on page 310. The TIMEOUT should cover the actual crystal startup time. Typically the time base used for the TIMEOUT counter is not as accurate as the time base accuracy that can be achieved for the LFTIMEOUT counter, specifically if that one is based on the LFXO timing. If LFTIMEOUT is triggered before TIMEOUT is triggered, then the LFTIMEOUTERR bitfield in CMU_IF will be set to 1. Note that use of LFTIMEOUT requires that the peripheral causing the wake-up is on the LFECLK domain. The intended use scenario is for example to wake up from EM2 by the RTCC triggering RAC wake-up via the PRS, which in turn can wake up the entire system. The RAC wake-up causes an automatic start of the HFXO in case the AUTOSTARTRDYSELRAC bit in CMU_HFXOCTRL is set to 1. Assertion of the HFXO ready signal, and therefore the radio start timing, can then be made deterministic by using LFTIMEOUT.

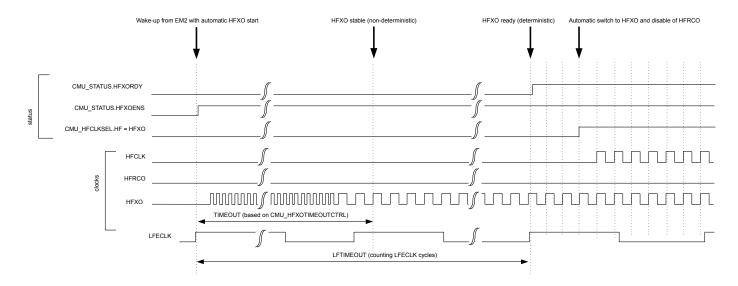

Figure 11.3. CMU Deterministic HFXO startup using LFTIMEOUT

The startup behavior of the HFXO also depends on how and how long the HFXO is disabled. This can be controlled by configuring the XTI2GND, and XTO2GND bitfields in the CMU_HFXOCTRL register.

## 11.3.2.3 Switching Clock Source

The HFRCO oscillator is a low energy oscillator with extremely short start-up time. Therefore, this oscillator is always chosen by hardware as the clock source for HFCLK when the device starts up (e.g., after reset and after waking up from EM2 Deep Sleep and EM3 Stop). After reset, the HFRCO frequency is 19 MHz.

Software can switch between the different clock sources at run-time. For example, when the HFRCO is the clock source, software can switch to HFXO by writing the field HF in the CMU_HFCLKSEL command register. See Figure 11.4 CMU Switching from HFRCO to HFXO before HFXO is ready on page 311 for a description of the sequence of events for this specific operation.

**Note:** Before switching the HFCLKSRC to HFXO via the HF bitfield in CMU_HFCLKSEL it is important to first enable the HFXO. Switching to a disabled oscillator will effectively stop HFSRCCLK and only a reset can recover the system.

When selecting an oscillator which has been enabled, but which is not ready yet, the HFSRCCLK will stop for the duration of the oscillator start-up time since the oscillator driving it is not ready. This effectively stalls the Core Modules and the High-Frequency Peripherals. It is possible to avoid this by first enabling the target oscillator (e.g., HFXO) and then waiting for that oscillator to become ready before switching the clock source. This way, the system continues to run on the HFRCO until the target oscillator (e.g., HFXO) has timed out and provides a reliable clock. This sequence of events is shown in Figure 11.5 CMU Switching from HFRCO to HFXO after HFXO is ready on page 312.

A separate flag is set when the oscillator is ready. This flag can also be configured to generate an interrupt.

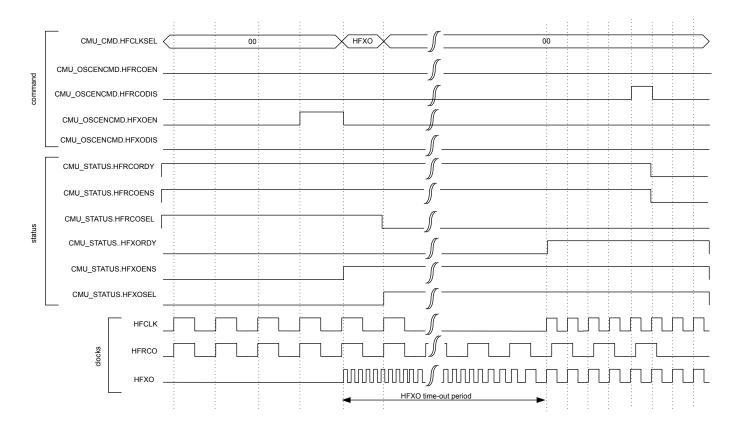

Figure 11.4. CMU Switching from HFRCO to HFXO before HFXO is ready

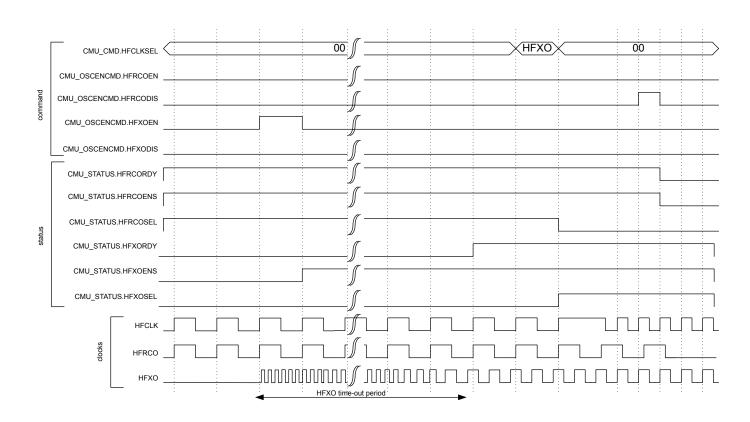

Figure 11.5. CMU Switching from HFRCO to HFXO after HFXO is ready

Switching clock source for LFACLK, LFBCLK, and LFECLK is done by setting the LFA, LFB and LFE bitfields in CMU_LFACLKSEL, CMU_LFBCLKSEL and CMU_LFECLKSEL respectively. To ensure no stalls in the Low Energy Peripherals, the clock source should be ready before switching to it.

Note: To save energy, remember to turn off all oscillators not in use.

## 11.3.2.4 HFXO Configuration

The High Frequency Crystal Oscillator needs to be configured to ensure safe startup for the given crystal. Refer to the device data sheet and application notes for guidelines in selecting correct components and crystals as well as for configuration trade-offs.

The HFXO crystal is connected to the HFXTAL N/HFXTAL P pins as shown in Figure 11.6 HFXO Pin Connection on page 313

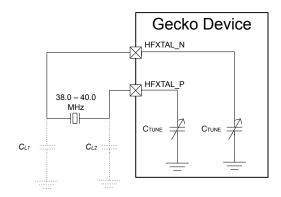

Figure 11.6. HFXO Pin Connection

By default the HFXO is started in crystal mode, but it is possible to connect an active external sine wave or square wave clock source to the HFXTAL_N pin of the HFXO. By configuring the MODE field in CMU_HFXOCTRL to EXTCLK, the HFXO can be bypassed and the source clock can be provided through the HFXTAL_N pin.

Upon enabling the HFXO, a hardware state machine sequentially applies the configurable startup state and steady state control settings from the CMU_HFXOSTARTUPCTRL and CMU_HFXOSTEADYSTATECTRL registers. Configuration is required for both the startup state and the steady state of the HFXO. After reaching the steady operation state of the HFXO, further optimization can optionally be performed to optimize the HFXO for noise and current consumption. Optimization for noise can be performed by an automatic Peak Detection Algorithm (PDA). Optimization for current can be performed by an automatic Shunt Current Optimization algorithm (SCO). HFXO operation is possible without PDA and SCO at the cost of higher noise and current consumption than required. Note that the HFXO circuit supports only crystals in the frequency range from 38-40 MHz, and is therefore only supported at voltage scale level 2. See 10.3.9 Voltage Scaling for more details.

Upon fully disabling the HFXO, the HFXTAL_N and HFXTAL_P pins can optionally be automatically pulled to ground as configured via the XTI2GND and XTO2GND bits respectively from the CMU_HFXOCTRL register. Do not set XTI2GND to 1 when the HFXO is in EXTCLK mode and an external wave is connected.

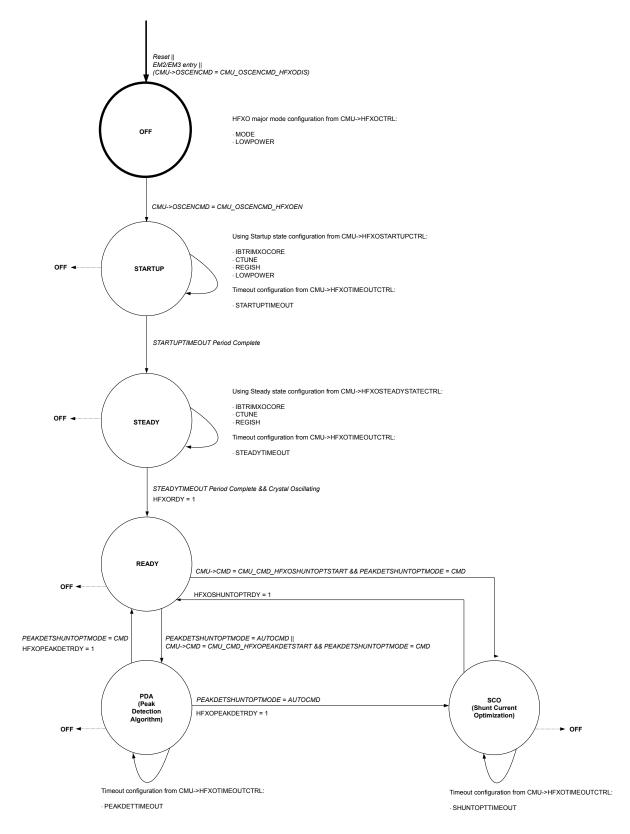

Figure 11.7. CMU HFXO Control State Machine

Refer to the device data sheet to find the configuration values for a given crystal. The startup state configuration needs to be written into the IBTRIMXOCORE and CTUNE bitfields of the CMU_HFXOSTARTUPCTRL register. The duration of the startup phase is configured in the STARTUPTIMEOUT bitfield of the CMU_HFXOTIMEOUTCTRL register. Similarly, the device data sheet provides the steady

state configuration depending on the crystal's CL, RESR and oscillation frequency. This configuration is programmed into the IBTRIM-XOCORE, REGISH and CTUNE bitfields of the CMU_HFXOSTEADYSTATECTRL register. The minimum duration of the steady phase is configured in the STEADYTIMEOUT bitfield of the CMU_HFXOTIMEOUTCTRL register.

All HFXO configuration needs to be performed prior to enabling the HFXO via HFXOEN in CMU_OSCENCMD unless noted otherwise. The HFXOENS flag in CMU_STATUS indicates if the HFXO has been successfully enabled. Once the HFXO startup time (STARTUP-TIMEOUT plus STEADYTIMEOUT) has exceeded and oscillations begin, the HFXO is ready for use as indicated by the HFXORDY flag in CMU_STATUS. If PDA and SCO are enabled, the HFXOPEAKDETRDY and HFXOSHUNTOPTRDY flags in the CMU_STATUS register indicate when these algorithms are ready and it is advised to also wait for these flags before using the HFXO.

The HFXO crystal bias current may be optimized and set to a value which decreases output phase noise without sacrificing PSR. This is done by programming the recommended IBTRIMXOCORE value into the CMU_HFXOSTEADYSTATECTRL register. The built-in Peak Detector Algorithm (PDA) performs further optimization to accommodate for process variations. Once PDA is ready as indicated by the HFXOPEAKDETRDY flag, the found optimal bias current setting is available in the IBTRIMXOCORE bitfield of the CMU_HFXOTRIMSTATUS register. This IBTRIMXOCORE setting should be saved and can be applied directly during a future HFXO startup as a low noise setting by programming it into the corresponding bitfield in CMU_HFXOSTEADYSTATECTRL while the HFXO is off.

If low noise is not required, the same PDA algorithm can be configured to optimize the HFXO for low current consumption by enabling LOWPOWER in the CMU_HFXOCTRL register before starting up the HFXO. The found IBTRIMXOCORE setting can be saved as a future low current setting.

Default PDA is started automatically once the HFXO has become ready. Repeated PDA can be triggered by writing HFXOPEAKDET-START to 1 in the CMU_CMD register. PDA can also be triggered only by the command register by configuring PEAKDETSHUNTOPT-MODE to CMD in the CMU_HFXOCTRL register before starting the HFXO. For PDA to work correctly, the REGISHUPPER bitfield of CMU_HFXOSTEADYSTATECTRL should be programmed to the value of the steady state REGISH + 3. The PEAKDETTIMEOUT bitfield in the CMU_HFXOTIMEOUTCTRL register is used to time the PDA steps and needs to be configured according to the device data sheet for the given crystal. The PEAKDETEN bitfield of the CMU_HFXOSTEADYSTATECTRL register is only used during manual (i.e. fully software controlled) peak detection and is ignored during automatic or command based triggering of the PDA. Note that the manual PDA mode is not recommended for general usage and therefore it is not further described. PDA should not be used when using an external wave as clock source.

Current consumption can be (further) reduced by running Shunt Current Optimization (SCO) after PDA. Once SCO is ready as indicated by the HFXOSHUNTOPTRDY flag, the found optimal regulator output current setting is available in the REGISH bitfield of the CMU_HFXOTRIMSTATUS register. This REGISH setting should be saved and can be applied directly during a future HFXO startup as a low current setting by programming it into the corresponding bitfield in CMU_HFXOSTEADYSTATECTRL while the HFXO is off. Normally SCO is run only for initial HFXO start up. The amplitude of the oscillator is not strongly dependent on temperature, but further optimization may be done each time that the temperature changes significantly. In that case, run SCO again by writing HFXOSHUNTOPTSTART to 1 in the CMU_CMD register. SCO depends on the LOWPOWER setting in the CMU_HFXOCTRL and needs to be rerun if that value has been changed. SCO should not be run when the HFXO is in use by the Radio Transceiver.

Default SCO is started automatically once the HFXO has become ready and PDA has finished. Repeated SCO can be triggered by writing HFXOSHUNTOPTSTART to 1 in the CMU_CMD register. SCO can also be triggered only by the command register by configuring PEAKDETSHUNTOPTMODE to CMD in the CMU_HFXOCTRL register before starting the HFXO. For SCO to work correctly, the REGISHUPPER bitfield of CMU_HFXOSTEADYSTATECTRL should be programmed to the value of the steady state REGISH + 3. The SHUNTOPTTIMEOUT bitfield in the CMU_HFXOTIMEOUTCTRL register is used to time the SCO steps and needs to be configured according to the device data sheet for the given crystal. The REGSELILOW bitfield of the CMU_HFXOSTEADYSTATECTRL register is only used during manual (i.e. fully software controlled) shunt current optimization and is ignored during automatic or command based triggering of the SCO. Note that the manual SCO mode is not recommended for general usage and therefore it is not further described.

#### 11.3.2.4.1 Automatic HFXO Start

The enabling of the HFXO and its selection as HFSRCCLK source can be performed automatically by hardware. Automatic HFXO enable and select can for example be used upon wake-up of the Radio Controller (RAC). Automatic control of the HFXO is controlled via the AUTOSTARTRDYSELRAC, AUTOSTARTSELEM0EM1 and AUTOSTARTEM0EM1 bits in the CMU_HFXOCTRL register. It further depends on the energy mode of the EFR32 and on the status of the RAC.

The HFXO autostart functionality is typically used when the RAC is used. The RAC module always requires the HFXO for its operation. The hardware requirement from RAC for an HFXO based HFSRCCLK is indicated in the HFXOREQ bitfield of the CMU_STATUS register. This requirement in itself does not lead to an automatic enable or select of the HFXO.

An automatic HFXO enable is performed only if any of the following conditions are met:

- EFR32 is in EM0/EM1 and AUTOSTARTEM0EM1 or AUTOSTARTSELEM0EM1 are set to 1.
- RAC is awake and AUTOSTARTRDYSELRAC is set to 1.

An automatic HFXO select is performed only if any of the following conditions is met:

- EFR32 is in EM0/EM1 and AUTOSTARTSELEM0EM1 is set to 1.
- RAC is awake, HFXO is ready, and AUTOSTARTRDYSELRAC is set to 1.

Whenever any of the conditions for automatic HFXO enable is met, software is not allowed to disable the HFXO. An attempt to do so (e.g., by writing 1 to the HFXODIS bit) is ignored and causes the HFXODISERR bit in the CMU_IF register to be set to 1. Similarly, whenever any of the conditions for automatic HFXO selection is met, software is not allowed to deselect the HFXO as clock source for HFSRCCLK. An attempt to do so (e.g., by selecting another clock source via CMU_HFCLKSEL) is ignored and causes the HFXODISERR bit in the CMU_IF register to be set to 1. Note that CMUERR is not implied by HFXODISERR. CMUERR will not get set to 1 for the above scenarios in which HFXODISERR gets set.

Software can only disable or deselect the HFXO after removing all of the HFXO automatic enable or select reasons. Note that if the autostart functionality is not used, software can always disable or deselect the HFXO even if hardware requires the HFXO as indicated via HFXOREQ bitfield in CMU_STATUS. The HFXODISERR flag will not get set in that case. The HFXO is only disabled by hardware upon EM2, EM3 or EM4 entry.

In case that AUTOSTARTSELEM0EM1 is set to 1 in EM0/EM1 (irrespective of the other autostart bits), the HFXO select will occur immediately, even if HFXO is not ready yet. Upon wake-up into EM0/EM1 this can therefore lead to a relatively long startup time as the system will not start operating from the HFRCO as it would otherwise do. In case of an automatic select triggered by the RAC (while AUTOSTARTSELEM0EM1 is set to 0), such a select will only occur upon the HFXO becoming ready and software can select and use another clock source in the mean time.

A typical use scenario of the AUTOSTARTRDYSELRAC bit is as follows. Set the AUTOSTARTRDYSELRAC bit in the CMU_HFXOCTRL register to 1 and set up the RTCC to periodically generate a compare match. Setup a PRS channel which uses this RTCC compare match as its source and allow the PRS channel to cause a wake-up into EM1. Setup the RAC to use the PRS channel as its source for TXEN or RXEN. Now, when the EFR32 is in EM2 and the RTCC generates a compare match, a wake-up into EM1 will occur and the HFXO will automatically start and become selected after which the RAC can perform its work and trigger a transition back into EM2 when done. The system started, used, and stopped the HFXO without ever being in EM0.

Note that the user should take care that the settings in the MSC_READCTRL and CMU_CTRL registers, as described in 11.3.3 Configuration for Operating Frequencies, are compatible with 40 MHz HFXO operation before enabling the HFXO automatic startup feature. A basic automatic HFXO start scenario is shown in Figure 11.8 CMU Automatic Startup and Selection of HFXO on page 317.

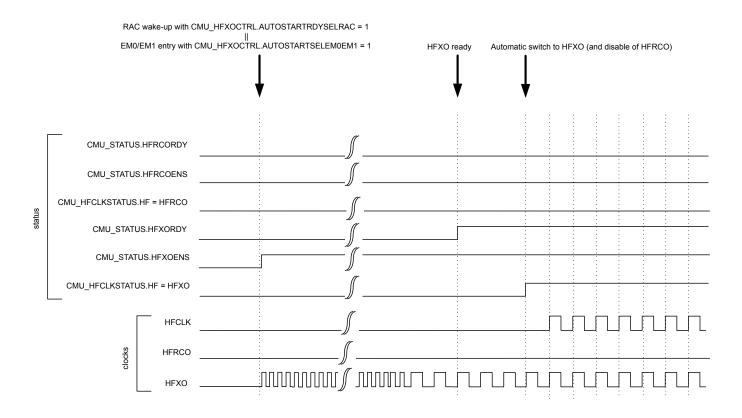

Figure 11.8. CMU Automatic Startup and Selection of HFXO

If an automatic selection of HFXO is performed, which switches the clock source used for HFSRCCLK, then the HFXOAUTOSW bit in CMU_IF is set to 1. After automatic enable and selection of the HFXO, the HFRCO is automatically disabled in case it is running. The disabling of a running HFRCO is signalled via the HFRCODIS bit in CMU_IF. This only applies to the HFRCO. If for example the LFXO was used as HFSRCCLK at the time of automatic selection of the HFXO, the LFXO remains unaffected.

The interaction between automatic HFXO startup and selection with startup and selection of HFRCO is shown in Figure 11.9 CMU HFRCO Startup/Selection While Awaiting Automatic HFXO Startup/Selection on page 317 and Figure 11.10 CMU Automatic HFXO startup/selection while HFRCO started/selected on page 318.

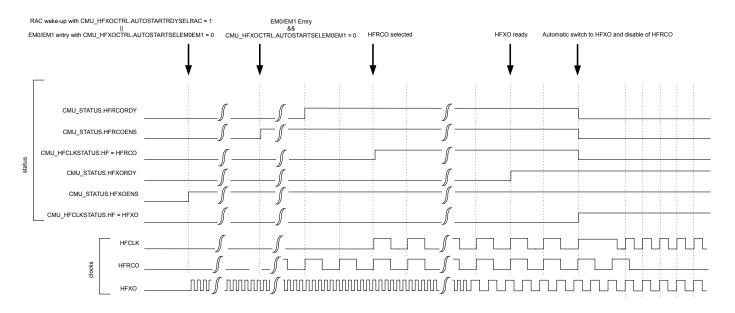

Figure 11.9. CMU HFRCO Startup/Selection While Awaiting Automatic HFXO Startup/Selection

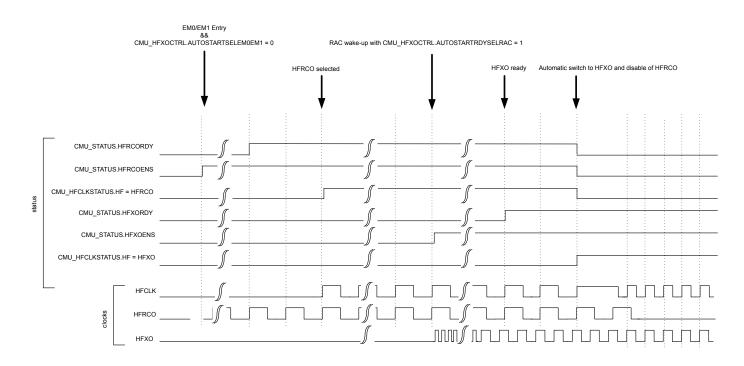

Figure 11.10. CMU Automatic HFXO startup/selection while HFRCO started/selected

## 11.3.2.5 LFXO Configuration

The Low Frequency Crystal Oscillator (LFXO) is default configured to ensure safe startup for all crystals. In order to optimize startup time and power consumption for a given crystal, it is possible to adjust the startup gain in the oscillator by programming the GAIN field in CMU LFXOCTRL. Recommendations for the GAIN setting are as follows:

- 1. C0 must be < 2 pF
- 2. For 12.5 pF < CL < 18 pF, GAIN = 3
- 3. For 8 pF < CL < 12.5 pF, GAIN = 2
- 4. For 6 pF < CL < 8 pF, GAIN = 1
- 5. For CL = 6 pF, GAIN = 0

Refer to the device data sheet and application notes for guidelines in selecting correct components and crystals as well as for configuration trade-offs.

The LFXO can be retained on in EM4 Hibernate/Shutoff. In that case its required configuration is latched/retained throughout EM4 even though the CMU_LFXOCTRL register itself will be reset. Upon EM4 exit, the CMU_LFXOCTRL register therefore needs to be reconfigured to its original settings and the LFXO needs to be restarted via CMU_OSCENCMD, before optionally unlatching the retained LFXO configuration by writing 1 to EM4UNLATCH in the EMU_CMD register. The LFXO startup time is configured via the TIMEOUT bitfield of the CMU_LFXOCTRL register. If the LFXO has been retained throughout EM4 Hibernate/Shutoff, it can be quickly restarted for use as LFACLK, LFBCLK or LFECLK by using its minimum TIMEOUT setting. While retained, the LFXO can be used down to EM4 Hibernate as the source for the LFECLK and down to EM4 Shutoff as the source for the CRYOCLK.

The LFXO crystal is connected to the LFXTAL_N/LFXTAL_P pins as shown in Figure 11.11 LFXO Pin Connection on page 319.

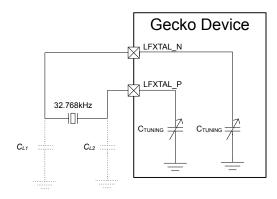

Figure 11.11. LFXO Pin Connection

By configuring the MODE field in CMU_LFXOCTRL, the LFXO can be bypassed, and an external clock source can be connected to the LFXTAL_N pin of the LFXO oscillator. If MODE is set to BUFEXTCLK, an external active sine source can be used as clock source. If MODE is set to DIGEXTCLK, an external active CMOS source can be used as clock source.

The LFXO includes on-chip tunable capacitance, which can replace external load capacitors. The TUNING bitfield of the CMU_LFXOCTRL register is used to tune the internal load capacitance connected between LFXTAL_P and ground and LFXTAL_N and ground symmetrically. The capacitance range and step size information is available in the device data sheets. Use the formula below to calculate the TUNING bitfield:

TUNING = ((desiredTotalLoadCap * 2 - Min(C_{LFXO T})) / C_{LFXO TS})

Figure 11.12. CMU LFXO Tuning Capacitance Equation

These tunable capacitors can also be used to compensate for temperature drift of the XTAL in software. Crystals normally have a temperature dependency which is given by a parabolic function. The crystal has highest frequency at its turnover temperature, normally 25C. The frequency is reduced following a parabola for higher and lower temperatures. The LFXO offers a mechanism to internally add capacitance on the LFXTAL_N and LFXTAL_P pins (in parallel to an optional external load capacitance). The variation in frequency as a function of temperature can therefore be compensated by adjusting the load capacitance. When the temperature compensation scheme is used, the maximum internal capacitance should be used to obtain good frequency matching at the turnover temperature. For higher and lower temperatures software then has the maximum range available to adjust the tuning. The external load capacitance

must then of course be reduced accordingly. Note that the ADC0 (26. ADC - Analog to Digital Converter) includes an embedded temperature sensor and that the EMU (10. EMU - Energy Management Unit) offers a temperature management interface, both of which can be used in combination with this LFXO temperature compensation scheme.

The XTAL oscillation amplitude can be controlled via the HIGHAMPL bitfield in CMU_LFXOCTRL. Setting HIGHAMPL to 1 will result in higher amplitude, which in turn provides safer operation, somewhat improved duty cycle, and lower sensitivity to noise at the cost of increased current consumption.

The AGC bit of the CMU_LFXOCTRL register is used to turn on or off the Automatic Gain Control module that adjusts the amplitude of the XTAL. When disabled, the LFXO will run at the startup current and the XTAL will oscillate rail to rail, again providing safer operation, improved duty cycle, and lower sensitivity to noise at the cost of increased current consumption.

## 11.3.2.6 HFRCO and AUXHFRCO Configuration

It is possible to calibrate the HFRCO and AUXHFRCO to achieve higher accuracy (see the device data sheets for details on accuracy). The frequency is adjusted by changing the TUNING and FINETUNING bitfields in CMU_HFRCOCTRL and CMU_AUXHFRCOCTRL. Changing to a higher value will result in a lower frequency. Refer to the data sheet for stepsize details.

The HFRCO can be set to one of several different frequency bands from 1 MHz to 38 MHz by setting the FREQRANGE field in CMU_HFRCOCTRL. Similarly the AUXHFRCO can be set to one of several different frequency bands from 1 MHz to 38 MHz by setting the FREQRANGE field in CMU_AUXHFRCOCTRL. The HFRCO and AUXHFRCO frequency bands are calibrated during production test, and the production tested calibration values can be read from the Device Information (DI) page. The DI page contains separate tuning values for various frequency bands. During reset, HFRCO and AUXHFRCO tuning values are set to the production calibrated values for the 19 MHz band, which is the default frequency band. When changing to a different HFRCO or AUXHFRCO band, make sure to also update the TUNING value and other bitfields in the CMU_HFRCOCTRL and CMU_AUXHFRCOCTRL registers. Typically the entire register is written with a value obtained from the Device Information (DI) page. Refer to 4.6 DI Page Entry Map for information on which frequency band settings are stored in the DI page.

The frequency can be tuned more accurately via the FINETUNING bitfield if fine tuning has been enabled via the FINETUNINGEN bit. Note that there will be a slight increase in the oscillator current consumption when fine tuning is enabled. Note also that changing the value of FINETUNINGEN will result in a frequency shift, regardless of the FINETUNING field value. If the oscillator is to be used at different times with fine tuning enabled and disabled, it should be tuned separately for both settings. The HFRCO and AUXHFRCO contain a local prescaler, which can be used in combination with any FREQRANGE setting. These prescalers allow the output clocks to be divided by 1, 2, or 4 as configured in the CLKDIV bitfield.

When using 11.3.2.8 RC Oscillator Calibration to tune HFRCO and AUXHFRCO to the desired frequency, linear search must be used to avoid over clocking the calibration counters. Before changing the FREQRANGE field in CMU_HFRCOCTRL, TUNING and FINE-TUNING fields should initially be set to the highest value (slowest frequency). After changing the FREQRANGE, linearly step TUNING value until desired frequency is reached. Likewise, before changing the TUNING field, FINETUNING field should initially be set to the highest value (lowest frequency). After changing the TUNING field, linearly step FINETUNING until accuracy is reached.

# 11.3.2.7 LFRCO Configuration

It is possible to calibrate the LFRCO to achieve higher accuracy (see the device data sheets for details on accuracy). The frequency is adjusted by changing the TUNING bitfield in CMU_LFRCOCTRL. Changing to a higher value will result in a lower frequency. Refer to the data sheet for stepsize details.

The LFRCO can be retained on in EM4 Hibernate/Shutoff. In that case its required configuration is latched/retained throughout EM4 even though the CMU_LFRCOCTRL register itself will be reset. Upon EM4 exit the CMU_LFRCOCTRL register therefore needs to be reconfigured to its original settings and the LFRCO needs to be restarted via CMU_OSCENCMD, before optionally unlatching the retained LFRCO configuration by writing 1 to EM4UNLATCH in the EMU_CMD register. The LFRCO startup time is configured via the TIMEOUT bitfield of the CMU_LFRCOCTRL register. Default its 16 cycle startup should be used. However, in case the LFRCO has been retained throughout EM4 Hibernate/Shutoff, it can be quickly restarted for use as LFACLK or LFBCLK by using its minimum TIMEOUT setting. While retained, the LFRCO can be used down to EM4 Hibernate as the source for the LFECLK and down to EM4 Shutoff as the source for the CRYOCLK.

The LFRCO is also calibrated in production and its TUNING values are set to the correct value during reset.

The LFRCO can be put in duty cycle mode by setting the ENVREF bit in CMU_LFRCOCTRL to 1 before starting the LFRCO. This will reduce current consumption, but will result in slightly worse accuracy especially at high temperatures. Setting the ENCHOP and/or ENDEM bitfields to 1 in the CMU_LFRCOCTRL register will improve the average LFRCO frequency accuracy at the cost of a worse cycle-to-cycle accuracy.

#### 11.3.2.8 RC Oscillator Calibration

The CMU has built-in HW support to efficiently calibrate the RC oscillators (LFRCO, HFRCO, AUXHFRCO, etc) at run-time. For a complete list of supported oscillators, refer to DOWNSEL and UPSEL fields in CMU_CALCTRL. See Figure 11.13 HW-support for RC Oscillator Calibration on page 321 for an illustration of this circuit. The concept is to select a reference and compare the RC frequency with the reference frequency. When the calibration circuit is started, one down-counter running on a selectable clock (DOWNSEL in CMU_CALCTRL) and one up-counter running on a selectable clock (UPSEL in CMU_CALCTRL) are started simultaneously. The top value for the down-counter must be written to CMU_CALCNT before calibration is started. The down-counter counts for CMU_CALCNT +1 cycles. When the down-counter has reached 0, the up-counter is sampled and the CALRDY interrupt flag is set. If CONT in CMU_CALCTRL is cleared, the counters are stopped after finishing the ongoing calibration. If continuous mode is selected by setting CONT in CMU_CALCTRL the down-counter reloads the top value and continues counting and the up-counter restarts from 0. Software can then read out the sampled up-counter value from CMU_CALCNT. The up-counter has counted (the sampled value)+1 cycles. The ratio between the reference and the oscillator subject to the calibration can easily be found using top+1 and sample+1. Overflows of the up-counter will not occur. If the up-counter reaches its top value before the down-counter reaches 0, the up-counter stays at its top value. Calibration can be stopped by writing CALSTOP in CMU_CMD. With this HW support, it is simple to write efficient calibration algorithms in software.

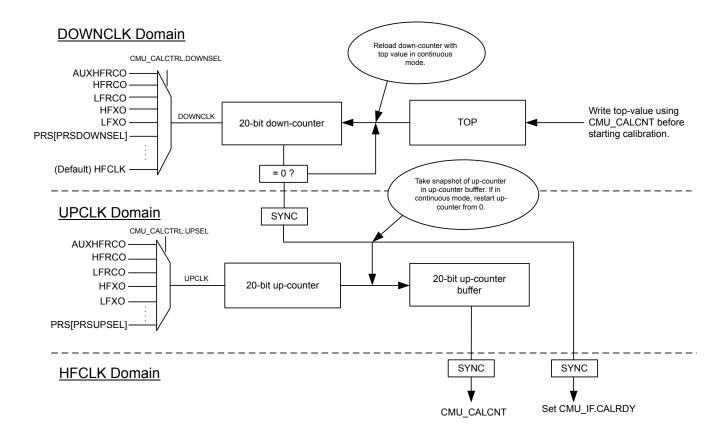

Figure 11.13. HW-support for RC Oscillator Calibration

The counter operation for single and continuous mode are shown in Figure 11.14 Single Calibration (CONT=0) on page 322 and Figure 11.15 Continuous Calibration (CONT=1) on page 322 respectively.

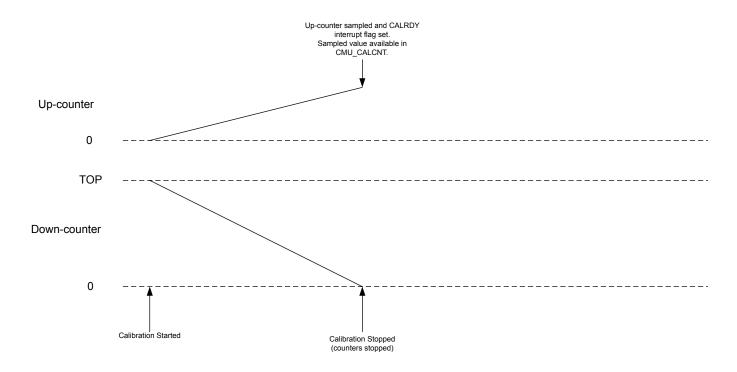

Figure 11.14. Single Calibration (CONT=0)

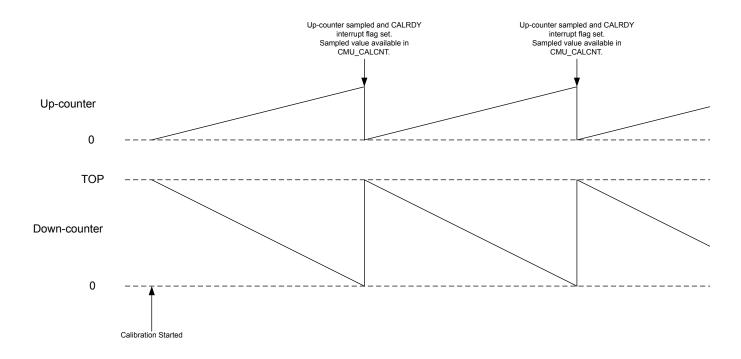

Figure 11.15. Continuous Calibration (CONT=1)

#### 11.3.3 Configuration for Operating Frequencies

The HFXO is capable of frequencies up to 40 MHz, which allows the EFR32 to run at up to this frequency. However the Memory System Controller (MSC) and the Low Energy Peripheral Interface need to be configured correctly to allow operation at higher frequencies as explained below.

The MODE bitfield in MSC_READCTRL makes sure the flash is able to operate at the given HFCLK frequency by inserting wait states for flash accesses. The required settings for controlling flash wait states are shown in Table 11.2 MSC Configuration for Operating Frequencies, at VSCALE2: Flash Wait States on page 323. The WSHFLE bitfield in CMU_CTRL is used to ensure that the Low Energy Peripheral Interface is able to operate at the given HFBUSCLK_{LE} frequency by inserting wait states when using this interface. The required settings are shown in Table 11.4 LE Configuration for Operating Frequencies: Low Energy Peripheral Interface on page 323.

The RAMxCACHEN bits in MSC_RAMCTRL enable RAM read caching on the specified bank. When RAM read caching is enabled, sequential addresses will be cached when the RAM is read, speeding up sequential accesses such as those typical of DMA operations. A RAM cache operation does require extra energy, so this feature should normally not be used when most accesses are expected to be non-sequential to save power. This feature is only available on certain RAM banks - refer to the MSC_RAMCTRL register definition.

Before going to a high frequency, make sure the registers in the table have the correct values. When going down in frequency, make sure to keep the registers at the values required by the higher frequency until after the switch has been done.

Table 11.2. MSC Configuration for Operating Frequencies, at VSCALE2: Flash Wait States

Condition	MODE in MSC_READCTRL
HFCLK <= 25 MHz	WS0 or above
25 MHz < HFCLK <= 40 MHz	WS1 or above

Table 11.3. MSC Configuration for Operating Frequencies, at VSCALE0: Flash Wait States

Condition	MODE in MSC_READCTRL
HFCLK <= 7 MHz	WS0 or above
7 MHz < HFCLK <= 14 MHz	WS1 or above
14 MHz < HFCLK <= 20 MHz	WS2

Table 11.4. LE Configuration for Operating Frequencies: Low Energy Peripheral Interface

Condition	WSHFLE in CMU_CTRL
HFBUSCLK _{LE} <= 32 MHz	0 / 1
HFBUSCLK _{LE} > 32 MHz	1

#### 11.3.4 Energy Modes

The availability of oscillators and system clocks depends on the chosen energy mode. Default the high frequency oscillators (HFRCO, AUXHFRCO, and HFXO) and high frequency clocks (HFSRCLK, HFCLK, HFCDRECLK, HFBUSCLK, HFPERCLK, HFRADIOCLK, HFCLKLE) are available downto EM1 Sleep. From EM2 Deep Sleep onwards these oscillators and clocks are normally off, although special cases exist as summarized in Table 11.5 Oscillator and Clock Availability in Energy Modes on page 324 and Table 10.2 EMU Energy Mode Overview on page 234. The CMU overview figure in Figure 11.1 CMU Overview - High Frequency Portion on page 301 and Figure 11.2 CMU Overview - Low Frequency Portion on page 302 also indicate which oscillators and clocks can be used in what energy modes.

The low frequency oscillators (LFRCO and LFXO) are available in all energy modes except in EM3 Stop when they are off by definition. Default these oscillators are also off in EM4 Hibernate and EM4 Shutoff, but they can be retained on in these states as well if needed. The ultra low frequency oscillator (ULFRCO) is default on in all energy modes, except for EM4 Shutoff, but it can be retained on in that mode as well if needed. The low frequency clocks (LFACLK, LFECLK, WDOGnCLK, and CRYOCLK) are in various power domains and therefore their availability not only depends on the chosen clock source, but also on the chosen energy mode as indicated in Table 11.5 Oscillator and Clock Availability in Energy Modes on page 324.

Table 11.5. Oscillator and Clock Availability in Energy Modes

	EM0 Active/EM1 Sleep	EM2 Deep Sleep	EM3 Stop	EM4 Hibernate	EM4 Shutoff
HFRCO	On ¹	Off	Off	Off	Off
HFXO	On ¹	Off	Off	Off	Off
AUXHFRCO	On ¹	On ²	On ²	Off	Off
LFRCO, LFXO	On ¹	On ¹	Off	Retained on ³	Retained on ³
ULFRCO	On	On	On	On	Retained on ³
HFSRCLK, HFCLK, HFCORECLK, HFBUSCLK, HFPERCLK, HFRA- DIOCLK, HFCLKLE	On ¹	Off	Off	Off	Off
AUXCLK	On ¹	On ²	On ²	Off	Off
ADCnCLK	On ¹	On ⁴	On ⁴	Off	Off
LFACLK, LFBCLK	On ¹	On ¹	On ⁵	Off	Off
LFECLK	On ¹	On ¹	On ⁵	Retained on ³	Off
WDOGnCLK	On ¹	On ¹	On ⁵	Off	Off
CRYOCLK	On ¹	On ¹	On ⁵	Retained on ³	Retained on ³

#### Note:

- 1. Under software control.
- 2. Default off, but kept active if used by the ADC.
- 3. Default off, but can be retained on.
- 4. Will be kept on if AUXHFRCO is selected as clock source.
- 5. On only if ULFRCO is used as clock source.

#### 11.3.5 Clock Output on a Pin

It is possible to configure the CMU to output clocks on the CMU_CLK0 and CMU_CLK1 pins. This clock selection is done using the CLKOUTSEL0 and CLKOUTSEL1 fields, respectively, in CMU_CTRL. The required output pins must be enabled in the CMU_ROUTEPEN register and the pin locations can be configured in the CMU_ROUTELOC0 register. The following clocks can be output on a pin:

- HFSRCCLK and HFEXPCLK. The HFSRCCLK is the high frequency clock before any prescaling has been applied. The HFEXPCLK
  is a prescaled version of HFCLK as controlled by the HFEXPPRESC bitfield in the CMU HFPRESC register.
- The unqualified clock output from any of the oscillators (ULFRCO, LFXO, HFXO). Note that these unqualified clocks can
  exhibit glitches or skewed duty-cycle during startup and therefore these clock outputs are normally not used before observing the
  related ready flag being set to 1 in CMU_STATUS.
- The qualified clock from any of the oscillators (ULFRCO, LFRCO, LFXO, HFXO, HFRCO, AUXHFRCO). A qualified clock will not
  have any glitches or skewed duty-cycle during startup. For LFRCO, LFXO and HFXO correct configuration of the TIMEOUT bitfield(s) in CMU_LFRCOCTRL, CMU_LFXOCTRL and CMU_HFXOTIMEOUTCTRL respectively is required to guarantee a properly
  qualified clock.

HFCLK will not have a 50-50 duty cycle when any other division factor than 1 is used in CMU_HFPRESC (i.e. if PRESC is not equal to 0). In such a case, the exported HFEXPCLK will therefore also not be 50-50 when its division factor is not set to an even number in CMU HFEXPPRESC.

#### 11.3.6 Clock Input From a Pin

It is possible to configure the CMU to input a low-frequency (< 1 MHz) clock from the CMU_CLKI0. This clock can be selected to drive HFSRCCLK reference using CMU_HFCLKSEL. The required input pin must be enabled in the CMU_ROUTEPEN register and the pin location can be configured in the CMU_ROUTELOC1 register.

#### 11.3.7 Clock Output on PRS

The CMU can be used as a PRS producer. It can output clocks onto PRS which can be selected by a consumer as CMUCLKOUT0 and CMUCLKOUT1. The clocks which can be produced via CMUCLKOUT0 and CMUCLKOUT1 are selected via the CLKOUTSEL0 and CLKOUTSEL1 fields, respectively, in CMU_CTRL.

Note that the CLKOUTSEL0 and CLKOUTSEL1 fields are also used for selecting which clock is output onto a pin as described in 11.3.5 Clock Output on a Pin. In contrast with clock output on a pin however, output of a clock onto PRS does not depend on any configuration of the CMU ROUTEPEN and CMU ROUTELOC0 registers.

#### 11.3.8 Error Handling

Certain restrictions apply to how and when the CMU registers can be configured as is described for the respective registers. Not adhering to these restrictions can lead to unpredictable and non-defined behaviour. Some of these software restrictions are checked in hardware and not adhering to them will cause the CMUERR interrupt flag in CMU_IF to be set to 1. The restrictions impacting CMUERR are as follows:

- CMU_HFRCOCTRL should not be written while HFRCOBSY in the CMU_SYNCBUSY register is set to 1.
- CMU AUXHFRCOCTRL should not be written while AUXHFRCOBSY in the CMU SYNCBUSY register is set to 1.
- CMU_HFXOSTARTUPCTRL, CMU_HFXOSTEADYSTATECTRL and CMU_HFXOTIMEOUTCTRL should not be written while
  HFXOBSY in the CMU_SYNCBUSY register is set to 1. Note that writes to CMU_HFXOCTRL do not impact CMUERR. Although
  most of its bitfields need to be configured before enabling the HFXO, it it allowed to change the AUTOSTART bits (i.e. AUTOSTARTRDYSELRAC, AUTOSTARTSELEM0EM1 and AUTOSTARTEM0EM1) at any time.
- HFXO should not be enabled before it has been properly disabled (so only enable HFXO when HFXOENS=0 or HFXOBSY=0). Likewise, HFXO should not be disabled before it has been properly enabled (so only disable HFXO when HFXOENS=1 or HFXOBSY=0).
- CMU_LFRCOCTRL should not be written while LFRCOBSY in the CMU_SYNCBUSY register is set to 1. The GMCCURTUNE bit-field should not be written with a differing value while the LFRCOVREFBSY flag is set to 1.
- CMU LFXOCTRL should not be written while LFXOBSY in the CMU SYNCBUSY register is set to 1.

#### 11.3.9 Interrupts

The interrupts generated by the CMU module are combined into one interrupt vector. If CMU interrupts are enabled, an interrupt will be made if one or more of the interrupt flags in CMU IF and their corresponding bits in CMU IEN are set.

### 11.3.10 Wake-up

The CMU can be (partially) active all the way down to EM4 Shutoff. It can wake up the CPU from EM2 upon LFRCO or LFXO becoming ready as LFRCORDY and LFXORDY can be used as wake-up interrupt.

#### 11.3.11 Protection

It is possible to lock the control- and command registers to prevent unintended software writes to critical clock settings. This is control-led by the CMU_LOCK register.

## 11.4 Register Map

The offset register address is relative to the registers base address.

Offset	Name	Туре	Description

### 11.5.2 CMU_HFRCOCTRL - HFRCO Control Register

Write this register to set the frequency band in which the HFRCO is to operate. Always update all fields in this register at once by writing the value for the desired band, which has been obtained from the Device Information page entry for that band. The TUNING, FINE-TUNING, FINETUNINGEN and CLKDIV bitfields can be used to tune a specific band (FREQRANGE) of the oscillator to a non-preconfigured frequency. When changing this setting there will be no glitches on the HFRCO output, hence it is safe to change this setting

even while the system is running on the HFRCO. Only write CMU_HFRCOCTRL when it is ready for an update as indicated by HFRCOBSY=0 in CMU_SYNCBUSY.

### 11.5.3 CMU_AUXHFRCOCTRL - AUXHFRCO Control Register

Write this register with the production calibrated values from the Device Info pages. The TUNING, FINETUNINGEN and CLKDIV bitfields can be used to tune a specific band (FREQRANGE) of the oscillator to a non-preconfigured frequency. Only write CMU_AUXHFRCOCTRL when it is ready for an update as indicated by AUXHFRCOBSY=0 in CMU_SYNCBUSY.

### 12. SMU - Security Management Unit

#### **Quick Facts**

### What?

The Security Management Unit (SMU) forms the control and status/reporting component of bus-level security in the EFR32xG12 Wireless Gecko.

#### Why?

Enables a robust and low-energy security solution at the system level

#### How?

Hardware context switching and access control provided via BLS components.

#### 12.1 Introduction

The Security Management Unit (SMU) peripheral adds hardware access control over all of the MCU peripherals that are managed by low level firmware integrated into a Real Timer Operating System (RTOS). The SMU is used in conjuntion with the Cortex-M operating modes (privileged and non-privileged) and the Memory Protection Unit (MPU). The EFR32xG12 Wireless Gecko MCUs include the ARM v7-M MPU that defines configurable access parameters to regions within the entire CPU memory map. The MPU is not covered in detail in this reference manual. For a complete description of the MPU registers etc, consult the ARM v7-M Architecture Reference Manual. The MPU can define up to 8 regions of varying sizes within the memory map, with each region also being able to be split into 8 equal sub-regions. Using these regions, firmware can define rules that enforce privileged and non-privileged accesses to different memory locations. For example, sections of flash can be marked as priviliged access, whereas other areas within the flash can be marked as having non-privileged mode access. Only privileged mode regions can access other privileged mode regions. Accesses attempted by a non-privileged region to a privileged region will cause a fault. The access permissions can be extended across the entire memory map including the peripheral region.

The Cortex-M starts up in privileged mode and the MPU is disabled after reset which means all regions in the memory map are accessble to the running application code. For many applications this is sufficient and the MPU remains disabled. However, when using a RTOS the kernel requires protection from user code and will switch to privileged mode and create tasks in non-privileged or thread mode. In addition, security is also a concern, so MCU peripherals should be protected to avoid security holes. Adding peripheral security to systems requires an increased number of MPU regions to protect areas such as the peripheral registers, including bit set/clear and bit banding regions. The defined regions are also dynamic based on the task requirements and in many cases the number of regions required exceeds the number of regions that can be enabled by the MPU.

The SMU is used to extend the access controls of each peripheral beyond the number of regions available using the MPU. The SMU peripheral registers provide the configuration and status bits for the Peripheral Protection Unit (PPU) to the CPU. The PPU is the underlying hardware component that operates on the low level bus interfaces within the SoC to derive the status for each peripheral.

### 12.2 Features

The main features of the SMU are as follows:

- · Contains control and status registers for hardware bus level component instances (e.g., the PPU)
- Simplifies RTOS context switching
  - · Hardware to complement any software context switching enabled by an MPU
  - Hardware-enforced access control extends capability of the v7-M MPU regions
  - · One bit control per peripheral reduces software overhead while dynamically modifying access permissions
- A configurable interrupt line that can be triggered from peripheral access fault events

### 12.3 Functional Description

An overview of the SMU module within the system is shown in Figure 12.1 Bus-Level Security System View on page 386.

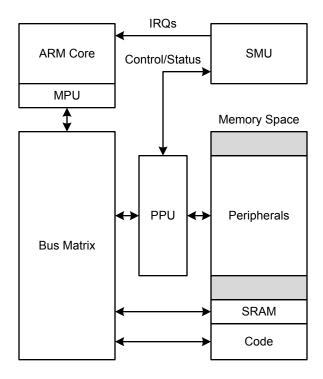

Figure 12.1. Bus-Level Security System View

### 12.3.1 PPU - Peripheral Protection Unit

The number of peripheral memory regions on the device exceeds the number of configurable regions available using the MPU. While it is possible to manage finer granularity of memory security through software, the PPU provides a hardware solution for fine-grained peripheral-level protection to eliminate the performance degradation associated with a partially software-managed solution.

The PPU provides a hardware access barrier to any peripheral that is configured to be protected. When an attempt is made to access a peripheral without the required privilege level, the PPU detects the fault and intercepts the access. No write or read of the peripheral register space occurs, and an all-zero value is returned if the access is a read. See 12.3.2.2 PPU Control for more details on how access faults are reported to the CPU.

**Note:** The CPU is the only system bus master in the EFR32xG12 Wireless Gecko that can trigger access faults. All other masters are given full access privileges and have no configurable context switching enabled.

### 12.3.2 Programming Model

The SMU does not provide any access control out of reset and needs to be configured by software. SMU access controls should be configured along with the MPU configuration. This is typically performed in a bootloader or other low level RTOS kernel/supervisor code prior to user code or other non-privileged code execution. At least one MPU region will be allocated to the entire peripheral region as a full access region (0x4000_0000 - 0x4006_FFFF). An RTOS kernel/supervisor can dynamically allocate peripheral accessibility by maintaining the hardware and software contexts available to each task. In the chart below there are mutiple tasks and the system switches between Task A and Task B via the RTOS handler. There are 16 peripherals shown in the example split between two regions. Task A has rights to access peripherals 0, 1, 4, 5 and 7, whereas task B has rights to access the complement of A (2, 3, and 6). After a Task B IRQ, the privileged OS handler is entered which signals the supervisor to reprogram the regions using the SMU based on an access control list. Control is then handed to Task B in non-privileged mode.

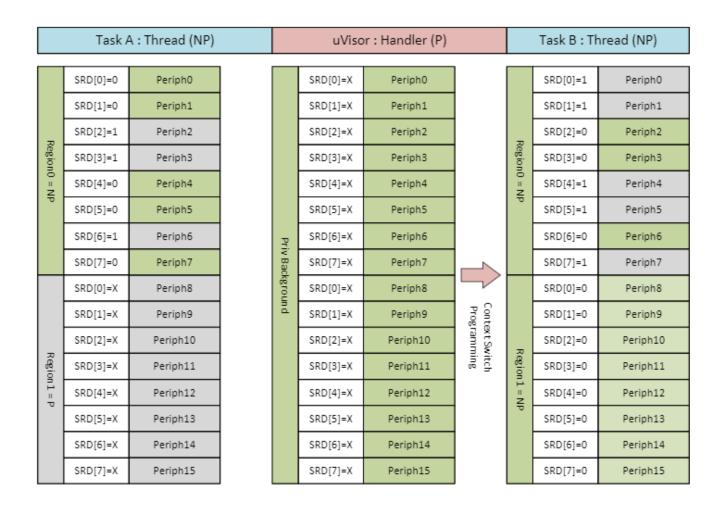

Figure 12.2. Peripheral Access Control Example

All hardware protections happen immediately in response to SMU configuration register writes without any latency cycles. However, since software instructions may be optimized or pipelined, it is important to make sure that software memory barrier instructions are used as needed after any SMU re-configuration before moving on or changing contexts. This ensures that the hardware context switch has taken full effect.

For the remainder of this section, the programming model is split into general SMU controls and component-specific controls (e.g., PPU).

### 12.3.2.1 Interrupt Control/Status

The SMU follows the standard EFR32xG12 Wireless Gecko interrupt programming model with SMU IF/IFS/IFC/IEN registers.

There is one interrupt bit PPUPRIV that will trigger on privilege faults detected by the PPU. Such fault mechanisms are configured as specified in 12.3.2.2 PPU Control.

### 12.3.2.2 PPU Control

The PPU_CTRL register provides an ENABLE bit that allows bypassing all PPU checking when set to 0. In this case, the rest of the PPU registers have no effect, and no access faults will occur. This is the reset state of the SMU.

When the ENABLE bit of PPU_CTRL register is asserted, access protection is configured on a peripheral-by-peripheral basis using the SMU_PPUPATDx register(s). Setting a bit in the SMU_PPUPATDx register to one configures the corresponding peripheral controlled by that bit to privileged access only. The single bit mode control for each peripheral provides fast hardware context switching for peripheral sharing, while still supporting fast software context switches for task-based CPU context switching.

**Note:** The SMU itself is a peripheral which has protection afforded by the PPU. A proper security/privilege context configuration requires setting of the SMU's access control bits properly at startup so that only a top-level task (e.g., a uVisor from ARM) can perform security/privilege context switches.

When a peripheral has access protection configured and the peripheral is accessed with invalid privilege credentials, then an access fault occurs. The corresponding interrupt flag in SMU_IF is asserted and the ID of the peripheral for which an unpriviliged access was attempted is captured in the PERIPHID bit-field of the PPU Fault Status register (SMU_PPUFS). This peripheral ID is held stable until all PPU interrupt flags are cleared to ensure that the first unprivileged access that caused the fault is not overwritten due to subsequent faults before being acknowledged by software.

**Note:** In the case of simultaneously occurring faults (which may be possible in some systems), only one of the faults' peripheral IDs will be captured. There is no inherent peripheral priority defined that would result in one peripheral being recognized before another.

### 12.4 Register Map

The offset register address is relative to the registers base address.

### 13. RTCC - Real Time Counter and Calendar

#### **Quick Facts**

### What?

The Real Time Counter and Calendar (RTCC) is a 32-bit counter ensuring timekeeping in low energy modes. The RTCC also includes a calendar mode for easy time and date keeping. In addition, the RTCC includes 128 bytes of general purpose retention data, allowing persistent data storage in all energy modes except EM4 Shutoff.

### Why?

Timekeeping over long time periods while using as little power as possible is required in many low power applications.

#### How?

A low frequency oscillator is used as clock signal and the RTCC has three different Capture/Compare channels which can trigger wake-up, generate PRS signalling, or capture system events. 32-bit resolution and selectable prescaling allow the system to stay in low energy modes for long periods of time and still maintain reliable timekeeping.

### 13.1 Introduction

The Real Time Counter and Calendar (RTCC) contains a 32-bit counter/calendar in combination with a 15-bit pre-counter to allow flexible prescaling of the main counter. The RTCC is available in all energy modes except EM4 Shutoff.

Three individually configurable Capture/Compare channels are available in the RTCC. These can be used to trigger interrupts, generate PRS signals, capture system events, and to wake the device up from a low energy mode. The RTCC also includes 128 bytes of general purpose storage and a Binary Coded Decimal (BCD) calendar mode, enabling easy time and date keeping.

### 13.2 Features

- · 32-bit Real Time Counter.
- 15-bit pre-counter, for flexible frequency scaling or for use as an independent counter.
- · EM4 Hibernate operation and wakeup.
- · 128 byte general purpose retention data.
- · Oscillator failure detection.
- Can continue through system reset; only reset by power loss, pin, or software reset.
- · Calendar mode.
  - · BCD encoding.
  - · Three programmable alarms.
  - · Leap year correction.
- · Three Capture/Compare registers.
  - Capture of PRS events from other parts of the system.
  - · Compare match or input capture can trigger interrupts.
  - Compare register 1, RTCC_CC1_CCV can be used as a top value for the main counter.
  - Compare register 0, RTCC_CC0_CCV can be used as a top value for the pre-counter.
  - · Compare match events are available to other peripherals through the Peripheral Reflex System (PRS).

### 13.3 Functional Description

The RTCC is a 32-bit up-counter with three Capture/Compare channels. In addition, the RTCC includes a 15-bit pre-counter which can be used as an independent counter or to prescale the main counter. An overview of the RTCC module is shown in Figure 13.1 RTCC Overview on page 399.

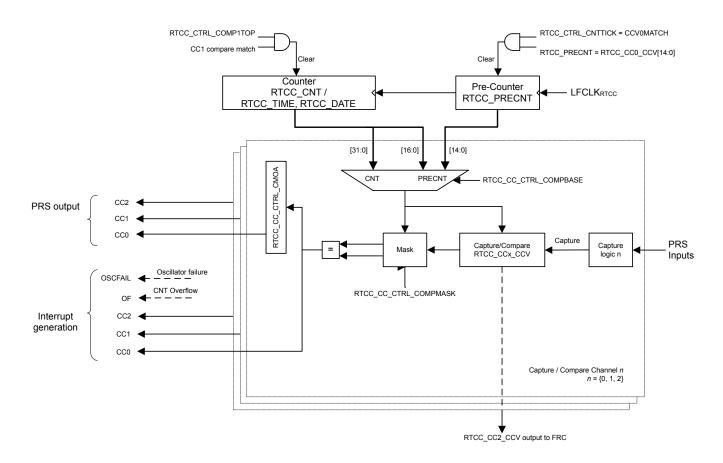

Figure 13.1. RTCC Overview

### 13.3.1 Counter

The RTCC consists of two counters; the 32-bit main counter, RTCC_CNT (RTCC_TIME and RTCC_DATE in calendar mode), and a 15-bit pre-counter, RTCC_PRECNT. The pre-counter can be used as an independent counter or to generate a specific frequency for the main counter. In both configurations, the pre-counter can be used to generate compare match events or be captured in the Capture/Compare channels as a result of an external PRS event. Refer to 13.3.2 Capture/Compare Channels for details on how to configure the Capture/Compare channels for use with the pre-counter.

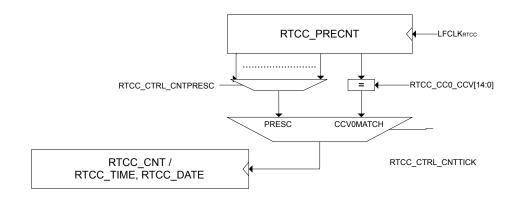

Figure 13.2. RTCC counters

The RTCC is enabled by setting the ENABLE bit in RTCC_CTRL. When the RTCC is enabled, the pre-counter (RTCC_PRECNT) increments upon each positive clock edge of LFCLK_{RTCC}. If CNTTICK in RTCC_CTRL is set to PRESC, the pre-counter will continue to count up, wrapping around to zero when it overflows. If CNTTICK in RTCC_CTRL is set to CCV0MATCH, the pre-counter will wrap around when it hits the value configured in RTCC_CCV.

The main counter of the RTCC, RTCC_CNT, has two modes; normal mode and calendar mode. In normal mode, the main counter is available in RTCC_CNT and increments upon each tick given from the pre-counter. Refer to 13.3.1.1 Normal Mode for a description on how to configure the frequency of these ticks. In calendar mode, the counter value is available in RTCC_TIME and RTCC_DATE, keeping track of seconds, minutes, hours, day of month, day of week, months, and years, all encoded in BCD format. Refer to 13.3.1.2 Calendar Mode for details on this mode. The mode of the main counter is configured in CNTMODE in RTCC_CTRL. The differences between the two modes are summarized below.

### Normal mode

- · Incremental counter, RTCC_CNT.
- RTCC_CCx_CCV used for Capture/Compare value.

### · Calendar mode

- BCD counters, RTCC_DATE, RTCC_TIME.
- RTCC CCx TIME and RTCC CCx DATE used for Capture/Compare value.

**Note:** The mode of the RTCC must be configured for CALENDAR mode in RTCC_CTRL_CNTMODE before writing to the mode dependent registers, RTCC_TIME, RTCC_DATE, RTCC_CCx_TIME, and RTCC_CCx_DATE. Writes to these registers when in NORMAL mode will be ignored.

#### 13.3.1.1 Normal Mode

The main counter can receive a tick based on different tappings from the pre-counter, allowing the ticks to be power of 2 divisions of the LFCLK_{RTCC}. For more accurate configuration of the tick frequency, RTCC_CC0_CCV[14:0] can be used as a top value for RTCC_PRECNT. When reaching the top value, the main counter receives a tick and the pre-counter wraps around. Table 13.1 RTCC Resolution Vs Overflow,  $F_{LFCLK}$  = 32768 Hz on page 401 summarizes the resolutions available when using a 32768 Hz oscillator as source for LFCLK_{RTCC}.

Table 13.1. RTCC Resolution Vs Overflow, F_{LFCLK} = 32768 Hz

RTCC_CTRL_CNTTICK	RTCC_CTRL_CNTPRESC	Main counter period, T _{CNT}	Overflow
CCV0MATCH	Don't care	(RTCC_CC0_CCV + 1)/F _{LFCLK} s	2 ³² *T _{CNT} seconds
	DIV1	30.5 µs	36.4 hours

	DIV32768	1 s	136 years

By default, the counter will keep counting until it reaches the top value, 0xFFFFFFF, before it wraps around and continues counting from zero. By setting CCV1TOP in RTCC_CTRL, a Capture/Compare channel 1 compare match will result in the main counter wrapping to 0. The timer will then wrap around on a channel 1 compare match (RTCC_CNT = RTCC_CC1_CCV). Before using the CCV1TOP setting, make sure to set this bit prior to or at the same time the RTCC is enabled. Setting CCV1TOP after enabling the RTCC (RTCC_CTRL_MODE != DISABLED) may cause unintended operation (e.g. if RTCC_CNT > RTCC_CC1_CCV, RTCC_CNT will wrap when reaching 0xFFFFFFFF rather than RTCC_CC1_CCV).

**Note:** If the RTCC is being reconfigured, and capture compare channel 1 has previously been used, a CCV1TOP wrap event might be pending. This would lead to the first tick of the main counter being a wrap to 0. To clear any pending wrap events, use the following procedure before reconfiguring the RTCC:

- 1. RTCC->CC[1].CTRL = RTCC_CC_CTRL_MODE_OFF;
- 2. RTCC->CTRL = RTCC_CTRL_CNTTICK_PRESC | RTCC_CTRL_CNTMODE_NORMAL | RTCC_CTRL_ENABLE;
- 3. rtcc_cnt_pre = RTCC->CNT;
- 4. while(RTCC->CNT == rtcc cnt pre);
- 5. Reconfigure the RTCC

#### 13.3.1.2 Calendar Mode

The RTCC includes a calendar mode which implements time and date decoding in hardware. Calendar mode is enabled by configuring CNTMODE in RTCC_CTRL to CALENDAR. When in calendar mode, the counter value is available in RTCC_TIME and RTCC_DATE. RTCC_TIME shows seconds, minutes, and hours while RTCC_DATE shows day of month, month, year, and day of week. RTCC_TIME and RTCC_DATE are encoded in BCD format. In calendar mode, the pre-counter should be configured to give ticks with a period of one second, i.e. RTCC_CTRL_CNTTICK should be set to PRESC, and the CNTPRESC bitfield of the RTCC_CTRL register should be set to DIV32768 if a 32768 Hz clock source is used.

In calendar mode, the time and date registers of the capture compare channels, RTCC_CCx_TIME and RTCC_CCx_DATE, are used to set compare values. Compare values can be set on seconds, minutes, hours, days, and months. Whether day of week or day of month is used for a Capture/Compare channel, it is configured in RTCC_CCx_CTRL_DAYCC of the respective Capture/Compare channel.

The RTCC will automatically compensate for 28-, 29- (leap year), 30-, and 31-day months. The day of week counter, RTCC_DATE_DAYOW, is a three bit counter incrementing when RTCC_TIME_HOURT overflows, wrapping around every seventh day. Automatic leap year correction, extending the month of February from 28 to 29 days every fourth year is by default enabled, but can be disabled by setting the LYEARCORRDIS bit in RTCC_CTRL. The pseudo-code for leap year correction is as follows:

```
if RTCC_DATE_YEARU modulo 2 = 0:
 if RTCC_DATE_YEARU modulo 4 = 0:
 leap_year = true
 else:
 leap_year = false
else:
 if (RTCC_DATE_YEARU + 2) modulo 4 = 0:
 leap_year = true
 else:
 leap_year = false
```

The seconds, minute, hour segments are represented in 24-hour BCD format. The month segments are enumerated as shown in Table 13.2 RTCC calendar enumeration on page 402.

Month RTCC_DATE_MONTHT RTCC_DATE_MONTHU 0b0001 January 0b0 0b0 0b0010 February March 0b0 0b0011 April 0b0 0b0100 May 0b0 0b0101 June 0b0 0b0110 0b0 0b0111 July August 0b0 0b1000 September 0b0 0b1001 0b1 0b0000 October November 0b1 0b0001 December 0b1 0b0010

Table 13.2. RTCC calendar enumeration

### 13.3.1.3 RTCC Initialization

The counters of the RTCC, RTCC_CNT (RTCC_TIME and RTCC_DATE in calendar mode) and RTCC_PRECNT, can at any time be written by software, as long as the registers are not locked using RTCC_LOCKKEY. All RTCC registers use the immediate synchronization scheme, described in 4.3.1 Writing.

**Note:** Writing to the RTCC_PRECNT register may alter the frequency of the ticks for the RTCC_CNT register.

### 13.3.2 Capture/Compare Channels

Three capture/compare channels are available in the RTCC. Each channel can be configured as input capture or output compare, by setting the corresponding MODE in the RTCC_CCx_CTRL register.

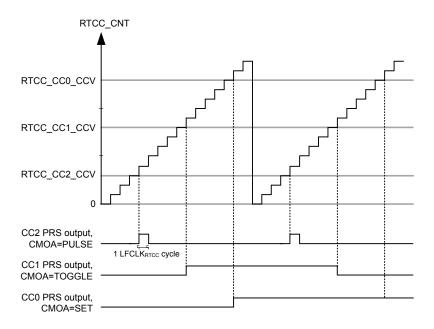

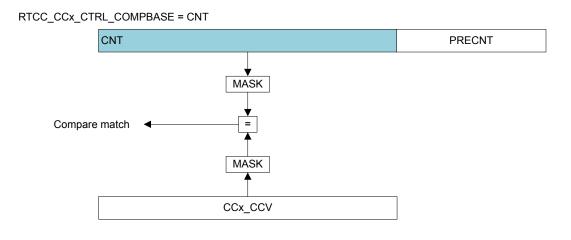

Figure 13.3. RTCC Compare match and PRS output illustration

In input capture mode the RTCC_CNT (RTCC_TIME and RTCC_DATE in calendar mode) register is captured into the RTCC_CCx_CCV (RTCC_CCx_TIME and RTCC_CCx_DATE in calendar mode) register when an edge is detected on the selected PRS input channel. The active capture edge is configured in the ICEDGE control bits.

In output compare mode the compare values are set by writing to the RTCC compare channel registers RTCC_CCx_CCV (RTCC_CCx_TIME and RTCC_CCx_DATE in calendar mode). These values will be compared to the main counter, RTCC_CNT (RTCC_TIME and RTCC_DATE in calendar mode), or a mixture of the main counter and the pre-counter, as illustrated in Figure 13.4 RTCC Compare base illustration on page 405. Compare base for the capture compare channels is set by configuring COMP-BASE in RTCC_CCx_CTRL.

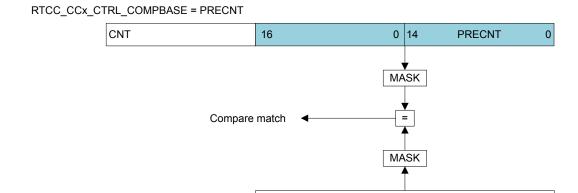

Figure 13.4. RTCC Compare base illustration

Table 13.3 RTCC Capture/Compare Subjects on page 405 summarizes which registers being subject to comparison for different configurations of RTCC_CTRL_CNTMODE and RTCC_CCx_CTRL_COMPBASE.

RTCC_CTRL_CNTMODE NORMAL CALENDAR

RTCC_CCx_CTRL_COMPBASE = RTCC_CNT vs. RTCC_CCx_CCV RTCC_DATE vs. RTCC_CCx_DATE

CCx_CCV

Table 13.3. RTCC Capture/Compare Subjects

Figure 13.5 RTCC Compare in calendar mode, COMPBASE = CNT on page 406 illustrates how the compare events are evaluated when in calendar mode with RTCC_CCx_CTRL_COMPBASE = CNT. The SECU, SECT, MINU, MINT, HOURU, HOURT, MONTHU, and MONTHT bitfields in RTCC_CCx_TIME and RTCC_CCx_DATE are compared to the corresponding bitfields in RTCC_DATE and RTCC_TIME. The DAYU and DAYT bitfields in RTCC_CCx_DATE will be compared to {RTCC_DATE_DAYOM}, RTCC_DATE_DAYU and DAYT bitfields in RTCC_CCx_DATE will be compared to {0b000, RTCC_DATE_DAYOW}.

{RTCC CNT[16:0],RTCC PRECNT[14:0]} vs.

RTCC_CCx_CCV

RTCC CCx CTRL COMPBASE =

**PRECNT** 

RTCC PRECNT vs. RTCC CCx CCV[14:0]

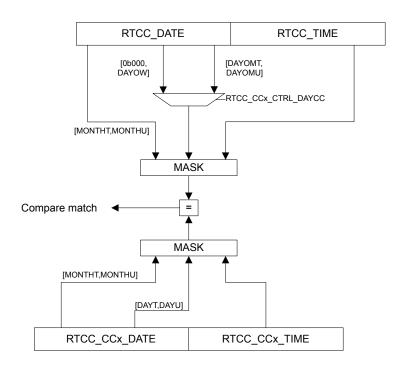

Figure 13.5. RTCC Compare in calendar mode, COMPBASE = CNT

To generate periodically recurring events, it is possible to mask out parts of the compare match values. By configuring COMPMASK in RTCC_CCx_CTRL, parts of the compare values will be masked out, limiting which part of the compare register being subject to comparison with the counter. Figure 13.6 RTCC Compare mask illustration, COMPMASK=11 on page 406 illustrates the effect of COMPMASK when in normal mode and calendar mode.

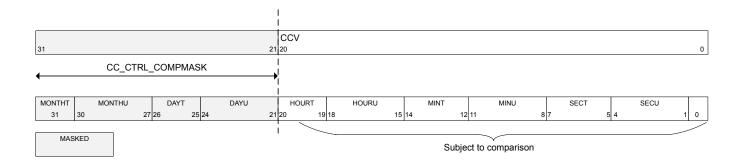

Figure 13.6. RTCC Compare mask illustration, COMPMASK=11

Upon a compare match, the respective Capture/Compare interrupt flag CCx is set. Additionally, the event selected by the CMOA setting is generated on the corresponding PRS output. This is illustrated in Figure 13.3 RTCC Compare match and PRS output illustration on page 404.

### 13.3.3 Interrupts and PRS Output

The RTCC has one interrupt for each of its 3 Capture/Compare channels, CC0, CC1, and CC2. Each Capture/Compare channel has a PRS output with configurable actions upon compare match.

The interrupt flag CNTTICK is set each time the main counter receives a tick (each second in calendar mode). In calendar mode, there are also interrupt flags being set each minute, hour, day, week, and month.

Upon oscillator failure detection, the OSCFAIL flag will be set.

### 13.3.3.1 Main Counter Tick PRS Output

To output the ticks for the main counter on PRS, it is possible to use a Capture/Compare channel and mask all the bits, i.e. RTCC_CCx_CTRL_COMPBASE=CNT and RTCC_CCx_CTRL_COMPMASK=31. PRS output of main counter ticks does not work if the main counter is not prescaled.

**Note:** To be able to mask all bits in the main counter, RTCC_CTRL_CNTMODE has to be set to CALENDAR. In NORMAL mode, the least significant bit can not be masked out.

### 13.3.4 Energy Mode Availability

The RTCC is available in all energy modes except EM4 Shutoff. To enable RTCC operation in EM4 Hibernate, the EMU_EM4CTRL register in the EMU has to be configured. Any enabled RTCC interrupt will wake the system up from EM4 Hibernate; if EM4WU in RTCC_EM4WUEN is set. Refer to 10. EMU - Energy Management Unit for details on how to configure the EMU.

### 13.3.5 Register Lock

To prevent accidental writes to the RTCC registers, the RTCC_LOCKKEY register can be written to any value other than the unlock value. To unlock the register, write the unlock value to RTCC LOCKKEY. Registers affected by this lock are:

- RTCC_CTRL
- RTCC PRECNT
- RTCC CNT
- RTCC TIME
- RTCC_DATE
- RTCC IEN
- RTCC POWERDOWN
- RTCC CCx CTRL
- RTCC CCx CCV
- RTCC_CCx_TIME
- RTCC_CCx_DATE

#### 13.3.6 Oscillator Failure Detection

To be able to detect OSC failure, the RTCC includes a security mechanism ensuring that at least three OSC cycles are detected within one period of the ULFRCO. If no OSC cycles are detected, the OSCFAIL interrupt flag is set. OSC failure detection is enabled by setting the OSCFDETEN bit in RTCC_CTRL.

### 13.3.7 Retention Registers

The RTCC includes 32 x 32 bit registers which can be retained in all energy modes except EM4 Shutoff. The registers are accessible through the RETx_REG registers. Retention is by default enabled in EM0 Active through EM4 Hibernate/Shutoff. The registers can be shut off to save power by setting the RAM bit in RTCC POWERDOWN.

Note: The retention registers are mapped to a RAM instance and have undefined state out of reset.

#### 13.3.8 Debug Session

By default, the RTCC is halted when code execution is halted from the debugger. By setting the DEBUGRUN bit in the RTCC_CTRL register, the RTCC will continue to run even when the debugger has halted the system.

# 13.4 Register Map

### 14. WDOG - Watchdog Timer

#### **Quick Facts**

### What?

The Watchdog Timer (WDOG) resets the system in case of a fault condition, and can be enabled in all energy modes as long as the low frequency clock source is available.

### Why?

If a software failure or external event renders the MCU unresponsive, a Watchdog timeout will reset the system to a known, safe state.

### How?

An enabled Watchdog Timer implements a configurable timeout period. If the CPU fails to re-start the Watchdog Timer before it times out, a full system reset will be triggered. The Watchdog consumes insignificant power, and allows the device to remain safely in low energy modes for up to 256 seconds at a time.

#### 14.1 Introduction

The purpose of the watchdog timer is to generate a reset in case of a system failure to increase application reliability. The failure can be caused by a variety of events, such as an ESD pulse or a software failure.

### 14.2 Features

- · Clock input from selectable oscillators
  - Internal 32 kHz LFRCO oscillator
  - Internal 1 kHz ULFRCO oscillator
  - External 32.768 kHz LFXO XTAL oscillator
  - HFCORECLK
- Configurable timeout period from 9 to 256k watchdog clock cycles
- · Individual selection to keep running or freeze when entering EM2 Deep Sleep or EM3 Stop
- · Selection to keep running or freeze when entering debug mode
- Selection to block the CPU from entering Energy Mode 4
- · Selection to block the CMU from disabling the selected watchdog clock
- Configurable warning interrupt at 25%,50%, or 75% of the timeout period
- Configurable window interrupt at 12.5%,25%,37.5%,50%,62.5%,75%,87.5% of the timeout period
- · Timeout interrupt
- · PRS as a watchdog clear
- Interrupt for the event where a PRS rising edge is absent before a software reset

#### 14.3 Functional Description

The watchdog is enabled by setting the EN bit in WDOGn_CTRL. When enabled, the watchdog counts up to the period value configured through the PERSEL field in WDOGn_CTRL. If the watchdog timer is not cleared to 0 (by writing a 1 to the CLEAR bit in WDOGn_CMD) before the period is reached, the chip is reset. If a timely clear command is issued, the timer starts counting up from 0 again. The watchdog can optionally be locked by writing the LOCK bit in WDOGn_CTRL. Once locked, it cannot be disabled or reconfigured by software.

When the EN bit in WDOGn_CTRL is cleared to 0, the watchdog counter is reset.

#### 14.3.1 Clock Source

Three clock sources are available for use with the watchdog, through the CLKSEL field in WDOGn_CTRL. The corresponding clocks must be enabled in the CMU. The SWOSCBLOCK bit in WDOGn_CTRL can be written to prevent accidental disabling of the selected clocks. Also, setting this bit will automatically start the selected oscillator source when the watchdog is enabled. The PERSEL field in WDOGn_CTRL is used to divide the selected watchdog clock, and the timeout for the watchdog timer can be calculated with the formula:

$$T_{TIMEOUT} = (2^{3+PERSEL} + 1) / f$$

where f is the frequency of the selected clock.

When the watchdog is enabled, it is recommended to clear the watchdog before changing PERSEL.

To use this module, the LE interface clock must be enabled in CMU HFBUSCLKEN0.

### 14.3.2 Debug Functionality

The watchdog timer can either keep running or be frozen when the device is halted by a debugger. This configuration is done through the DEBUGRUN bit in WDOGn CTRL. When code execution is resumed, the watchdog will continue counting where it left off.

### 14.3.3 Energy Mode Handling

The watchdog timer can be configured to either keep on running or freeze when entering EM2 Deep Sleep or EM3 Stop. The configuration is done individually for each energy mode in the EM2RUN and EM3RUN bits in WDOGn_CTRL. When the watchdog has been frozen and is re-entering an energy mode where it is running, the watchdog timer will continue counting where it left off. For the watchdog there is no difference between EM0 Active and EM1 Sleep. The watchdog does not run in EM4 Hibernate/Shutoff. If EM4BLOCK in WDOGn_CTRL is set, the CPU will be prevented from entering EM4 Hibernate/Shutoff by software request.

#### Note:

If the WDOG is clocked by the LFXO or LFRCO, writing the SWOSCBLOCK bit will prevent the CPU from entering EM3 Stop. When running from the ULFRCO, writing the SWOSCBLOCK bit will prevent the CPU from entering EM4 Hibernate/Shutoff.

### 14.3.4 Register Access

Since this module is a Low Energy Peripheral, and runs off a clock which is asynchronous to the HFCORECLK, special considerations must be taken when accessing registers. Refer to 4.3 Access to Low Energy Peripherals (Asynchronous Registers) for a description on how to perform register accesses to Low Energy Peripherals. Note that clearing the EN bit in WDOGn_CTRL will reset the WDOG module, which will halt any ongoing register synchronization.

### Note:

Never write to the WDOG registers when it is disabled, except to enable the watchdog by setting the EN bitfield in WDOGn_CTRL.

### 14.3.5 Warning Interrupt

The watchdog implements a warning interrupt which can be configured to occur at approximately 25%, 50%, or 75% of the timeout period through the WARNSEL field of the WDOGn_CTRL register. This interrupt can be used to wake up the cpu for clearing the watchdog. The warning point for the watchdog timer can be calculated with the formula:

$$T_{WARNING} = ((2^{3+PERSEL}) * (WARNSEL / 4) + 1) / f,$$

where f is the frequency of the selected clock.

When the watchdog is enabled, it is recommended to clear the watchdog before changing WARNSEL.

### 14.3.6 Window Interrupt

This interrupt occurs when the watchdog is cleared below a certain threshold. This threshold is given by the formula:

$$T_{WARNING} = ((2^{3+PERSEL}) * (WINSEL/8) + 1)/f,$$

where f is the frequency of the selected clock.

This value will be approximately 12.5%, 25%, 37.5%, 50%, 62.5%, 75%, or 87.5% of the timeout value based on the WINSEL field of the WDOGn_CTRL. Figure 14.2 WDOG Warning, Window, and Timeout on page 429 illustrates the warning, the window, and the timeout interrupts. Also, it shows where the prs rising edge needs to happen. The prs edge detection feature is discussed later.

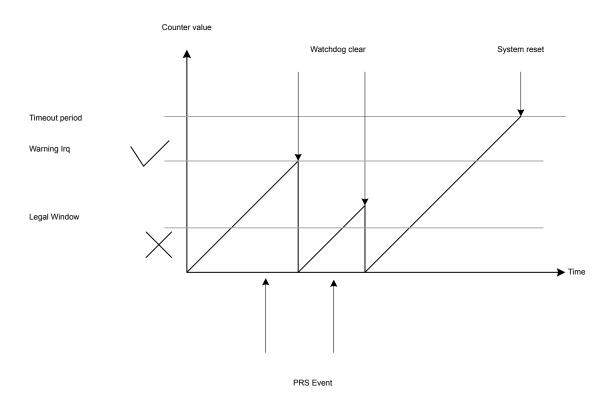

Figure 14.2. WDOG Warning, Window, and Timeout

When the watchdog is enabled, it is recommended to clear the watchdog before changing WINSEL.

### 14.3.7 PRS as Watchdog Clear

The first PRS channel (selected by register WDOGn_PCH0_PRSCTRL) can be used to clear the watchdog counter. To enable this feature, CLRSRC must be set to 1. Figure 14.2 PRS Clearing WDOG on page 430 shows how the PRS channel takes over the WDOG clear function. Clearing the WDOG with the PRS is mutually exclusive of clearing the WDT by software.

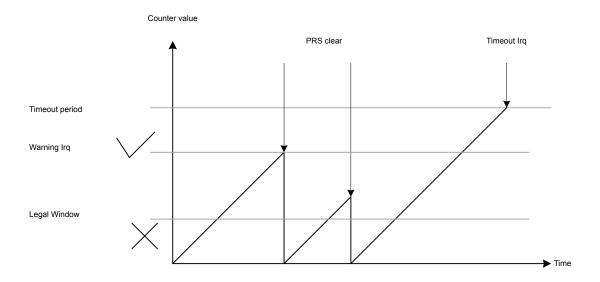

Figure 14.2. PRS Clearing WDOG

### 14.3.8 PRS Rising Edge Monitoring

PRS channels can be used to monitor multiple processes. If enabled, every time the watch dog timer is cleared the PRS channels are checked and any channel which has not seen an event can trigger an interrupt.

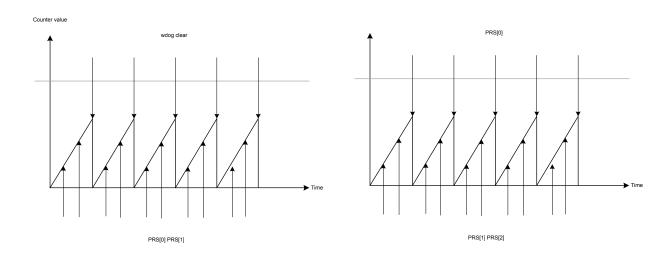

Figure 14.3. PRS Edge Monitoring in WDOG

### 15. PRS - Peripheral Reflex System

#### **Quick Facts**

#### What?

The Peripheral Reflex System (PRS) allows configurable, fast, and autonomous communication between peripherals.

### Why?

Events and signals from one peripheral can be used as input signals or triggered by other peripherals. Besides, PRS reduces latency and ensures predictable timing by reducing software overhead and thus current consumption.

#### How?

Without CPU intervention the peripherals can send Reflex signals (both pulses and level) to each other in single or chained steps. The peripherals can be set up to perform actions based on the incoming Reflex signals. This results in improved system performance and reduced energy consumption.

### 15.1 Introduction

The Peripheral Reflex System (PRS) is a network allowing direct communication between different peripheral modules without involving the CPU. Peripheral modules which send out Reflex signals are called producers. The PRS routes these Reflex signals through Reflex channels to consumer peripherals which perform actions depending on the Reflex signals received. The format for the Reflex signals is not given, but edge triggers and other functionality can be applied by the PRS.

#### 15.2 Features

- · 12 Configurable Reflex Channels
  - · Each channel can be connected to any producing peripheral, including the PRS channels
  - · Consumers can choose which channel to listen to
  - Selectable edge detector (Rising, falling and both edges)
  - Configurable AND and OR between channels
  - · Optional channel invert
  - · PRS can generate event to CPU
  - · Two independent DMA requests based on PRS channels
- · Software controlled channel output
  - · Configurable level
  - Triggered pulses

#### 15.3 Functional Description

An overview of the PRS module is shown in Figure 15.1 PRS Overview on page 443. The PRS contains 12 Reflex channels. All channels can select any Reflex signal offered by the producers. The consumers can choose which PRS channel to listen to and perform actions based on the Reflex signals routed through that channel. The Reflex signals can be both edge signals and level signals.

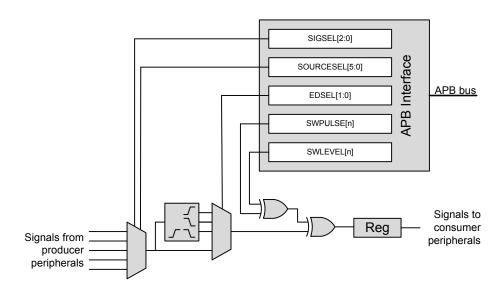

Figure 15.1. PRS Overview

#### 15.3.1 Channel Functions

Different functions can be applied to a Reflex signal within the PRS. Each channel includes an edge detector to enable generation of pulse signals from level signals. The PRS channels can also be manually triggered by writing to PRS_SWPULSE or PRS_SWLEVEL. SWLEVEL[n] is a programmable level for each channel and holds the value it is programmed to. Setting SWPULSE[n] will cause the PRS channel to output a high pulse that is one HFCLK cycle wide. The SWLEVEL[n] and SWPULSE[n] signals are then XOR'ed with the selected input from the producers to form the output signal sent to the consumers listening to the channel. For example, when SWLEVEL[n] is set, if a producer produces a signal of 1, this will cause a channel output of 0.

#### 15.3.1.1 Operational Mode

Reflex channels can operate in two modes, synchronous or asynchronous. In synchronous mode Reflex signals are clocked on the HFCLK, and can be used by any Reflex consumer. However, this will not work in EM2/EM3, since the HFCLK will be turned off.

Asynchronous Reflex channels are not clocked on HFCLK, and can be used even in EM2/EM3. However, the asynchronous mode can only be used by a subset of the Reflex consumers.

The asynchronous Reflex signals generated by the producers are indicated in the SIGSEL field of PRS_CHx_CTRL register. The consumers capable of utilizing asynchronous Reflex signals include the LEUART and the PCNT. The USART can also utilize some particular asynchronous signals. Refer to the respective modules for details on how to configure them to use the PRS.

**Note:** If a Reflex channel with ASYNC field of PRS_CHx_CTRL register set to '1' is used in a consumer not supporting asynchronous reflexes, the behaviour is undefined

#### 15.3.1.2 Edge Detection and Clock Domains

Using EDSEL in PRS_CHx_CTRL, edge detection can be applied to a PRS signal. When edge detection is enabled, changes in the PRS input will result in a pulse on the PRS channel. This requires that the ASYNC bit in PRS_CHx_CTRL is cleared. Signals on the PRS input must be at least one HFCLK period wide in order to be detected properly. This applies to all cases when ASYNC is not used in the PRS.

For communication between peripherals on different prescaled clocks (e.g. between peripherals on HFCLK and HFPERCLK), there are two options. One option is to use level signals. No additional action is needed for level signals, but software must make sure that the level signals are held long enough for the destination domain to detect them. The other option is to use pulse signals. For pulse signals, edge detection should be enabled (by configuring EDSEL in PRS_CHx_CTRL to positive edge, negative edge, or both) and STRETCH in PRS_CHx_CTRL should be set. When edge detection and stretch are enabled on a PRS source, the output on the PRS channel is held long enough for the destination domain to detect the pulse. This also works if there are multiple destination domains running at different frequencies.

### 15.3.1.3 Configurable PRS Logic

Each PRS channel has three logic functions that can be used by themselves or in combination. The selected PRS source can be AND'ed with the next PRS channel output, OR'ed with the previous PRS channel output and inverted. This is shown in Figure 15.1 PRS Overview on page 443. The order of the functions is important. If OR and AND are enabled at the same time, AND is applied first, and then OR. Note that the previous and next channel options wrap around. Using the ORPREV option on the first PRS channel OR's with the output of the last PRS channel. Likewise, using the ANDNEXT option on the last PRS channel AND's with the output of the first PRS channel.

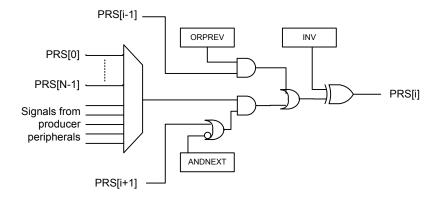

Figure 15.2. Configurable PRS Logic

In addition to the logic functions that can combine a PRS channel with one of its neighbors, a PRS channel can also select any other PRS channel as input. This can allow relatively complex logic functions to be created.

### 15.3.2 Producers

Through SOURCESEL in PRS_CHx_CTRL, each PRS channel selects signal producers. Each producer outputs one or more signals which can be selected by setting the SIGSEL field in PRS_CHx_CTRL. Setting the SOURCESEL bits to 0 (Off) leads to a constant 0 output from the input mux. An overview of the available producers can be found in the SOURCESEL and SIGSEL fields in PRS_CHx_CTRL. Note that GPIO producers are selected in the GPIO module using the edge interrupt configuration settings described in 32.3.5.1 Edge Interrupt Generation. GPIOPIN0 uses the selection for the EXTI0 interrupt, GPIOPIN1 uses the selection for the EXTI1 interrupt, and so on.

### 15.3.3 Consumers

Consumer peripherals (Listed in Table 15.1 Reflex Consumers on page 445) can be set to listen to a PRS channel and perform an action based on the signal received on that channel. While most consumers can handle either only pulse input or only level input, some can handle both pulse and level inputs.

Table 15.1. Reflex Consumers

Module	Reflex Input	Input Format
TIMER	Compare/Capture Channel	Pulse / Level
	Alternate Input for DTI (Available only in specific TIMERs See data sheet for details)	Level
	Alternate Input for DTI Fault 0 (Available only in specific TIMERs See data sheet for details)	Level

	Stop LETIMER	Pulse
	Clear LETIMER	Pulse
RTCC	Compare/Capture Channel	Pulse/Level
PRS	Set Event	Pulse
	DMA Request 0	Pulse
	DMA Request 1	Pulse
CAPSENSE	Start Conversion	Pulse

#### 15.3.4 Event on PRS

The PRS can be used to send events to the MCU. This is very useful in combination with the Wait For Event (WFE) instruction. A single PRS channel can be selected for this using SEVONPRSSEL in PRS_CTRL, and the feature is enabled by setting SEVONPRS in the same register.

Using SEVONPRS, one can e.g. set up a timer to trigger an event to the MCU periodically, every time letting the MCU pass through a WFE instruction in its program. This can help in performance-critical sections where timing is known, and the goal is to wait for an event, then execute some code, then wait for an event, then execute some code and so on.

### 15.3.5 DMA Request on PRS

Up to two independent DMA requests can be generated by the PRS. The PRS signals triggering the DMA requests are selected using the LDMA_CHx_REQSEL register, by setting SOURCESEL to PRS and SIGSEL to either PRSREQ0 or PRSREQ1. The DMA requests are cleared when the DMA services the requests. The requests are set whenever the selected PRS signals are high.

The selected PRS signals must have ASYNC cleared when they are used as inputs to the DMA. Edge detection in the PRS can be enabled to only trigger transfers on edges.

### 15.3.6 Example

The example below (illustrated in Figure 15.3 TIMER0 Overflow Starting ADC0 Single Conversions Through PRS Channel 5. on page 447) shows how to set up ADC0 to start single conversions every time TIMER0 overflows (one HFPERCLK cycle high pulse), using PRS channel 5:

- Set SOURCESEL in PRS CH5 CTRL to TIMER0 as input to PRS channel 5.
- Set SIGSEL in PRS CH5 CTRL to select the overflow signal (TIMER00F from TIMER0).
- · Configure ADC0 with the desired conversion set-up.
- Set SINGLEPRSEN in ADC0_SINGLECTRL to 1 to enable single conversions to be started by a high PRS input signal.
- Set SINGLEPRSSEL in ADC0_SINGLECTRL to 0x5 to select PRS channel 5 as input to start the single conversion.
- Start TIMER0 with the desired TOP value, an overflow PRS signal is output automatically on overflow. Note that the ADC results needs to be fetched either by the CPU or DMA.

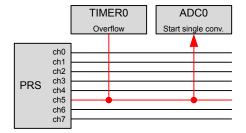

Figure 15.3. TIMER0 Overflow Starting ADC0 Single Conversions Through PRS Channel 5.

### 16. PCNT - Pulse Counter

### **Quick Facts**

### What?

The Pulse Counter (PCNT) decodes incoming pulses. The module has a quadrature mode which may be used to decode the speed and direction of a mechanical shaft. PCNT can operate in EM0 Active down to EM3 Stop.

### Why?

The PCNT generates an interrupt after a specific number of pulses (or rotations), eliminating the need for timing or I/O interrupts and CPU processing to measure pulse widths, etc.

#### How?

PCNT uses the LFACLK or may be externally clocked from a pin. The module incorporates a 16-bit up/down-counter to keep track of incoming pulses or rotations.

## 16.1 Introduction

The Pulse Counter (PCNT) can be used for counting incoming pulses on a single input or to decode quadrature encoded inputs in EM0 Active down to EM3 Stop. It can run from the internal LFACLK while counting pulses on the PCNTn_S0IN pin. Or, alternately, the PCNTn S0IN pin may be used as an external clock source that runs both the PCNT counter and register access.

## 16.2 Features

- · 16-bit counter with reload register
- · Auxiliary counter for counting a single direction
- · Single input oversampling up/down counter mode
- Externally clocked single input pulse up/down counter mode
- · Quadrature decoder modes
  - Externally clocked quadrature decoder 1X mode
  - · Oversampling quadrature decoder 1X, 2X and 4X modes
- · Interrupt on counter underflow and overflow
- · Interrupt when a direction change is detected (quadrature decoder mode only)
- · Optional pulse width filter
- · Optional input inversion/edge detect select
- · Optional inputs from PRS
- · Asynchronously triggered compare and clear

### 16.3 Functional Description

An overview of the PCNT module is shown in Figure 16.1 PCNT Overview on page 470.

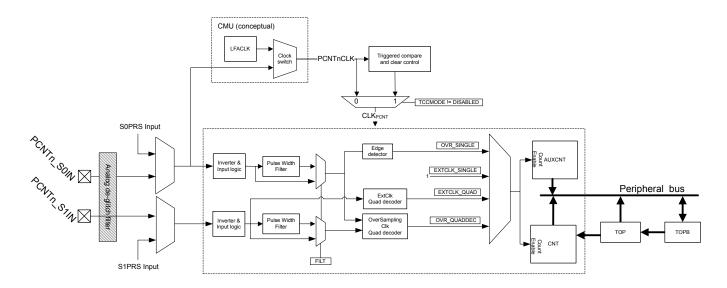

Figure 16.1. PCNT Overview

### 16.3.1 Pulse Counter Modes

The pulse counter can operate in single input oversampling mode (OVSSINGLE), externally clocked single input counter mode (EXTCLKSINGLE), externally clocked quadrature decoder mode (EXTCLKQUAD) and oversampling quadrature decoder modes(OVSQUAD1X, OVSQUAD2X and OVSQUAD4X). The following sections describe operation of each of these modes and how they are enabled. Input timing constraints are described in 16.3.6 Clock Sources and 16.3.7 Input Filter.

## 16.3.1.1 Single Input Oversampling Mode

This mode is enabled by writing OVSSINGLE to the MODE field in the PCNTn_CTRL register and disabled by writing DISABLE to the same field. The LFACLK clock source to the pulse counter is configured by clearing PCNT0CLKSEL in the CMU_PCNTCTRL in the Clock Management Unit (CMU).

The optional pulse width filter is enabled by setting the FILT bit in the PCNTn_CTRL register. Additionally, the PCNTn_S0IN input may be inverted, so that falling edges are counted, by setting the EDGE bit in the PCNTn_CTRL register.

If S1CDIR in the PCNTn_CTRL register is cleared, PCNTn_S0IN is the only observed input in this mode. The PCNTn_S0IN input is sampled by the LFACLK and the number of detected positive or negative edges on PCNTn_S0IN appears in PCNTn_CNT. The counter may be configured to count down by setting the CNTDIR bit in PCNTn_CTRL. Default is to count up.

The counting direction can also be controlled externally in this mode by setting S1CDIR. This will make the input value on PCNTn_S1IN decide the direction counted on a PCNTn_S0IN edge. If PCNTn_S1IN is high, the count is done according to CNTDIR in PCNTn_CTRL. If low, the count direction is opposite.

### 16.3.1.2 Externally Clocked Single Input Counter Mode

This mode is enabled by writing EXTCLKSINGLE to the MODE field in the PCNTn_CTRL register and disabled by writing DISABLE to the same field. The external pin clock source is configured by setting PCNT0CLKSEL in the CMU_PCNTCTRL register (11. CMU - Clock Management Unit ).

Positive edges on PCNTn_S0IN are used to clock the counter. Similar to the oversampled mode, PCNTn_S1IN is used to determine the count direction if S1CDIR is set. If not, CNTDIR in PCNTn_CTRL solely defines count direction.

The digital pulse width filter is not available in this mode. The analog de-glitch filter in the GPIO pads is capable of removing some unwanted noise. However, this mode may be susceptible to spikes and unintended pulses from devices such as mechanical switches, and is therefore most suited to take input from electronic sensors etc. that generate single wire pulses.

### 16.3.1.3 Quadrature Decoder Modes

Two different types of quadrature decoding is supported in the pulse counter: the externally clocked (Asynchronous) quadrature decoding and the oversampling (Synchronous) quadrature decoding. The externally clocked mode supports 1X quadrature decoding whereas the oversampling mode supports 1X, 2X and 4X quadrature decoding. These modes are described in detail in 16.3.1.4 Externally Clocked Quadrature Decoder Mode and 16.3.1.5 Oversampling Quadrature Decoder Mode.

### 16.3.1.4 Externally Clocked Quadrature Decoder Mode

This mode is enabled by writing EXTCLKQUAD to the MODE field in PCNTn_CTRL and disabled by writing DISABLE to the same field. The external pin clock source is configured by setting PCNT0CLKSEL in the CMU_PCNTCTRL register (11. CMU - Clock Management Unit ).

In this mode, both edges on PCNTn_S0IN pin are used to sample PCNTn_S1IN pin, in order to decode the quadrature code. A quadrature coded signal contains information about the relative speed and direction of a rotating shaft as illustrated by Figure 16.2 PCNT Quadrature Coding on page 472, hence the direction of the counter register PCNTn_CNT is controlled automatically.

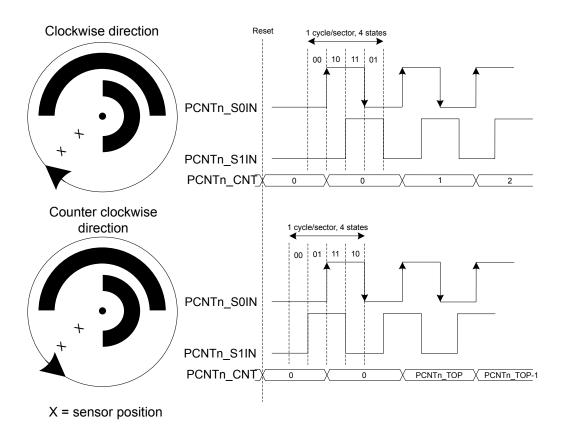

Figure 16.2. PCNT Quadrature Coding

If PCNTn_S0IN leads PCNTn_S1IN in phase, the direction is clockwise, and if it lags in phase the direction is counter-clockwise. Default behavior is illustrated by Figure 16.2 PCNT Quadrature Coding on page 472.

The counter direction may be read from the DIR bit in the PCNTn_STATUS register. Additionally, the DIRCNG interrupt in the PCNTn_IF register is generated when a direction change is detected. When a change is detected, the DIR bit in the PCNTn_STATUS register must be read to determine the current new direction.

**Note:** The sector disc illustrated in the figure may be finer grained in some systems. Typically, they may generate 2-4 PCNTn_S0IN wave periods per 360° rotation.

The direction of the quadrature code and control of the counter is generated by the simple binary function outlined by Table 16.1 PCNT QUAD Mode Counter Control Function on page 472. Note that this function also filters some invalid inputs that may occur when the shaft changes direction or temporarily toggles direction.

**Table 16.1. PCNT QUAD Mode Counter Control Function** 

Inputs		Control/Status	
S1IN posedge	S1IN negedge	Count Enable	CNTDIR status bit
0	0	0	0

Inputs		Control/Status	
S1IN posedge	S1IN negedge	Count Enable	CNTDIR status bit
0	1	1	0
1	0	1	1
1	1	0	0

**Note:** PCNTn_S1IN is sampled on both edges of PCNTn_S0IN.

### 16.3.1.5 Oversampling Quadrature Decoder Mode

There are three Oversampling Quadrature Decoder Modes supported: 1X , 2X and 4X. These modes are enabled by writing OVS-QUAD1X, OVSQUAD2X and OVSQUAD4X, respectively, to the MODE field in PCNTn_CTRL and disabled by writing DISABLE to the same field. The LFACLK clock source to the pulse counter must be configured by clearing PCNT0CLKSEL in the CMU_PCNTCTRL in the Clock Management Unit (CMU), 11. CMU - Clock Management Unit .

The optional pulse width filter is enabled by setting the FILT bit in the PCNTn_CTRL register. The filter applies to both inputs PCNTn_S0IN and PCNTn_S1IN. The filter length is configured by FILTLEN in PCNTn_OVSCFG register.

Based on the modes selected, the decoder updates the counter on different events. In the OVSQUAD1X mode, the counter is updated on the rising edge of the PCNTn_S0IN input when counting up, and on the negedge of the PCNTn_S0IN input when counting down. In the OVSQUAD2X mode, the counter is updated on both edges of PCNTn_S0IN input. In the OVSQUAD4X mode the counter is updated on both edges of both inputs PCNTn_S0IN and PCNTn_S1IN. Table 16.2 PCNT OVSQUAD 1X, 2X and 4X Mode Counter Control Function on page 474 outlines the increment or decrement of the counter based on the Quadrature Mode selected.

**Note:** The decoding behavior of OVSQUAD1X mode is slightly different compared to EXTCLKQUAD mode(also 1X mode). In the EXTCLKQUAD mode, the counter is updated only on the posedge of S0IN input. However, in the OVSQUAD1X mode, the counter is updated on the posedge of S0IN when counting up and on the negedge of S0IN when counting down.

Table 16.2. PCNT OVSQUAD 1X, 2X and 4X Mode Counter Control Function

Direction	Previou	ıs State	Next :	State	OVSQUAD MODE							
	S1IN	SOIN	S1IN	SOIN	1X	2X	4X					
	0	0	0	1	+1	+1	+1					
Clockwise	0	1	1	1			+1					
Ciockwise	1	1	1	0		+1	+1					
	1	0	0	0			+1					
	1	0	1	1		-1	-1					
Counter Clock-	1	1	0	1			-1					
wise	0	1	0	0	-1	-1	-1					
	0	0	1	0			-1					

Figure 16.3 PCNT State Transitions for Different Oversampling Quadrature Decoder Modes on page 475 illustrates the different states of the quadrature input and the state transitions that updates the counter for the different modes. Each cycle of the input states results in 1 update, 2 updates and 4 updates of the counter for OVSQUAD1X, OVSQUAD2X and OVSQUAD4X modes respectively.

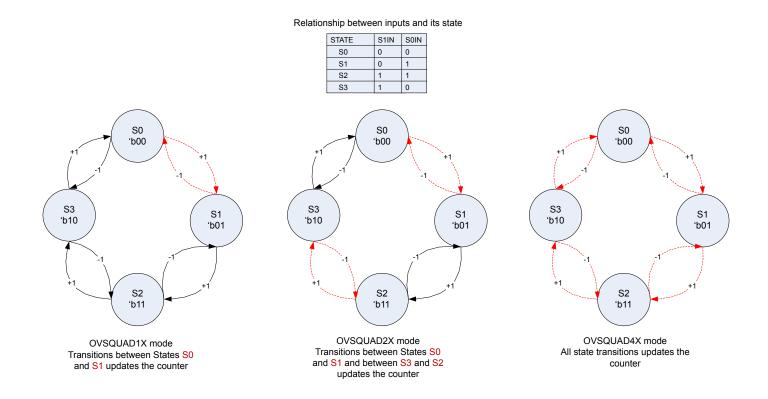

Figure 16.3. PCNT State Transitions for Different Oversampling Quadrature Decoder Modes

The counter direction can be read from the DIR bit in PCNTn_STATUS register. Additionally, the DIRCNG interrupt in the PCNTn_IF is generated when the direction change is detected. When a change is detected, the DIR bit in the PCNTn_STATUS register must be read to determine the new direction.

In the oversampling quadrature decoder modes, the maximum input toggle frequency supported is 8KHz. For frequencies of 8KHz and higher, incorrect decoding occurs. The different decoding modes and the counter updates are further illustrated by Figure 16.4 PCNT Oversampling Quadrature Decoder 1X Mode on page 475, Figure 16.5 PCNT Oversampling Quadrature Decoder 2X Mode on page 476 and Figure 16.6 PCNT Oversampling Quadrature Decoder 4X Mode on page 476.

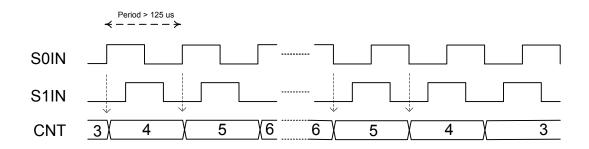

Figure 16.4. PCNT Oversampling Quadrature Decoder 1X Mode

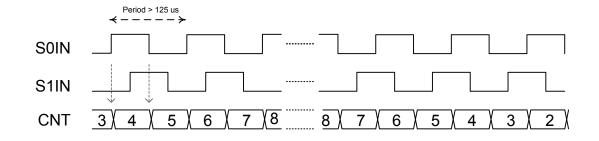

Figure 16.5. PCNT Oversampling Quadrature Decoder 2X Mode

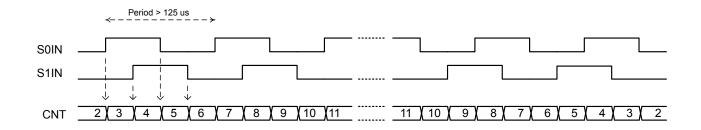

Figure 16.6. PCNT Oversampling Quadrature Decoder 4X Mode

The above modes, by default are prone to flutter effects in the inputs PCNTn_S0IN and PCNTn_S1IN. When this occurs, the counter changes directions rapidly causing DIRCNG interrupts and unnecessarily waking the core. To prevent this, set FLUTTERRM in PCNTn_OVSCFG register. When enabled, flutter is removed, thus preventing unnecessary wakeup of the core. The flutter removal logic works by preventing update of the counter value if the wheel keeps changing direction as a result of flutter. The counter is only updated if the current and previous state transition of the rotation are in the same direction. These state transitions are quadrature decoder mode specific. The highlighted state transitions in Figure 16.3 PCNT State Transitions for Different Oversampling Quadrature Decoder Modes on page 475 are the ones considered for the different quadrature decoder modes. Figure 16.7 PCNT Oversampling Quadrature Decoder with Flutter Removal on page 476 shows how the counter is updated for the different quadrature decoder modes with flutter removal FLUTTERRM enabled in PCNTn OVSCFG.

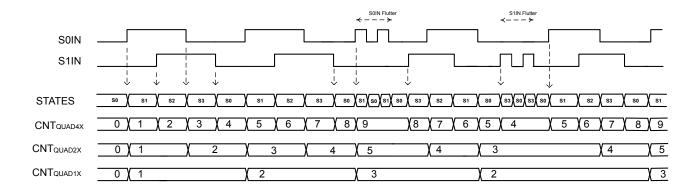

Figure 16.7. PCNT Oversampling Quadrature Decoder with Flutter Removal

### 16.3.2 Hysteresis

By default the pulse counter wraps to 0 when passing the configured top value, and wraps to the top value when counting down from 0. On these events, a system will likely want to wake up to store and track the overflow count. This is fine if the pulse counter is tracking a monotonic value or a value that does not change directions frequently. In the latter scenario, if the counter changes directions around the overflow/underflow point, the system will have to wake up frequently to keep track of the rotations, resulting in higher current consumption.

To solve this, the pulse counter has a way of introducing hysteresis to the counter. When HYST in PCNTn_CTRL is set, the pulse counter will always wrap to TOP/2 on underflows and overflows. This takes the counter away from the area where it might overflow or underflow, removing the problem. Figure 16.8 PCNT Hysteresis behavior of Counter on page 477 illustrates the hysteresis behavior.

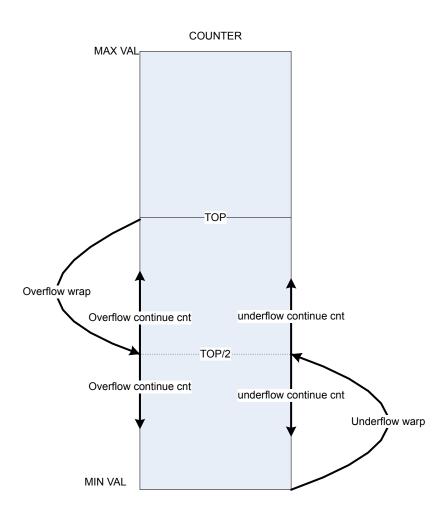

Figure 16.8. PCNT Hysteresis behavior of Counter

Given a starting value of 0 for the counter, the absolute count value when hysteresis is enabled can be calculated with the equations Figure 16.9 Absolute Position With Hysteresis and Even TOP Value on page 477 or Figure 16.10 Absolute Position With Hysteresis and Odd TOP Value on page 477, depending on whether the TOP value is even or odd.

Figure 16.9. Absolute Position With Hysteresis and Even TOP Value

$$CNT_{abs} = CNT - UF_{CNT} x (TOP/2+1) + OF_{CNT} x (TOP/2+2)$$

Figure 16.10. Absolute Position With Hysteresis and Odd TOP Value

### 16.3.3 Auxiliary Counter

To be able to keep explicit track of counting in one direction in addition to the regular counter which counts both up and down, the auxiliary counter can be used. The pulse counter can, for instance, be configured to keep track of the absolute rotation of the wheel, while at the same time the auxiliary counter can keep track of how much the wheel has reversed.

The auxiliary counter is enabled by configuring AUXCNTEV in PCNTn_CTRL. It will always count up, but it can be configured whether it should count up on up-events, down-events or both, keeping track of rotation either way or general movement. The value of the auxiliary counter can be read from the PCNTn_AUXCNT register.

Overflows on the auxiliary counter happen when the auxiliary counter passes the top value of the pulse counter, configured in PCNTn_TOP. In that event, the AUXOF interrupt flag is set, and the auxiliary counter wraps to 0.

As the auxiliary counter, the main counter can be configured to count only on certain events. This is done through CNTEV in PCNTn_CTRL, and it is possible like for the auxiliary counter, to make the main counter count on only up and down events. The difference between the counters is that where the auxiliary counter will only count up, the main counter will count up or down depending on the direction of the count event.

### 16.3.4 Triggered Compare and Clear

The pulse counter features triggered compare and clear. When enabled, a configurable trigger will induce a comparison between the main counter, PCNTn_CNT, and the top value, PCNTn_TOP. After the comparison, the counter is cleared. The trigger for a compare and clear event is configured in the TCCMODE bit-field in PCNTn_CTRL. There are two options, LFA and PRS. If LFA is selected, the pulse counter will be compared with the top value, and cleared every 2^N LFA clock cycle (where N is the value of TCCPRESC in PCNTn_CTRL). If a PRS trigger is selected, the active PRS channel is configured in TCCPRSSEL in PCNTn_CTRL. The PRS input can be inverted by setting TCCPRSPOL, triggering the compare and clear on the negative edge of the PRS input. The PRS input can also be used as a gate for the pulse counter clock. This is enabled by setting PRSGATEEN in PCNTn_CTRL.

**Note:** When PRSGATEEN is set, the clock to the entire pulse counter will be gated by the PRS input, meaning that register writes will not take effect while the gated clock is inactive.

Comparison with PCNTn_TOP can be performed in three ways: range, greater than or equal, and less than or equal. TCCCOMP in PCNTn_CTRL configures comparison mode. Upon a compare match, the TCC interrupt is set, and the PRS output from the pulse counter is set. The PRS output will remain set until the next compare and clear event. Triggered compare and clear is intended for use when the pulse counter is configured to count up. In this mode, PCNTn_CNT will not wrap to 0 when hitting PCNTn_TOP, it will keep counting. In addition, the counter will not overflow, it will rather stop counting, just setting the overflow interrupt flag.

Figure 16.11 PCNT Triggered Compare and Clear on page 479 shows an overview of the control circuitry for triggered compare and clear. The control circuitry includes two positive edge detectors (PED) and glitch filters, used to generate clocks for the pulse counter. The two clock outputs are mutually exclusive: If both edge detectors receive a pulse at the same time, the output pulse from one of them will be postponed until the other edge detectors output pulse has completed.

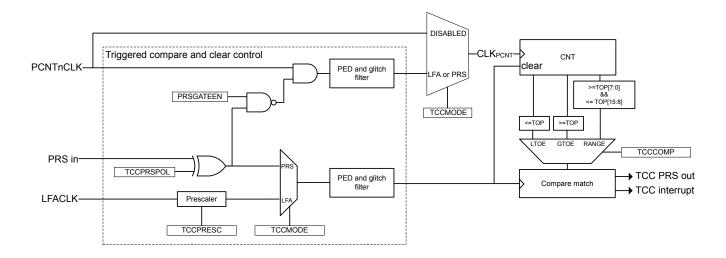

Figure 16.11. PCNT Triggered Compare and Clear

**Note:** TCCMODE, TCCPRESC, PRSGATEEN, TCCPRSPOL, and TCCPRSSEL in PCNTn_CTRL should only be altered when RSTEN in PCNTn_CTRL is set.

### 16.3.5 Register Access

The counter-clock domain may be clocked externally. To update the counter-clock domain registers from software in this mode, 2-3 clock pulses on the external clock are needed to synchronize accesses to the externally clocked domain. Clock source switching is controlled from the registers in the CMU (11. CMU - Clock Management Unit ).

When the RSTEN bit in the PCNTn_CTRL register is set, the PCNT clock domain is asynchronously held in reset. The reset is synchronously released two PCNT clock edges after the RSTEN bit in the PCNTn_CTRL register is cleared by software. This asynchronous reset restores the reset values in PCNTn_TOP, PCNTn_CNT and other control registers in the PCNT clock domain.

CNTRSTEN works in a similar manner as RSTEN, but only resetting the counter, CNT. Note that the counter is also reset by RSTEN.

AUXCNTRSTEN works in a similar manner as RSTEN, but only resetting the auxiliary counter, PCNTn_AUXCNT. Note that the auxiliary counter is also reset by RSTEN.

Since this module is a Low Energy Peripheral, and runs off a clock which is asynchronous to the HFCORECLK, special considerations must be taken when accessing registers. Refer to 4.3 Access to Low Energy Peripherals (Asynchronous Registers) for a description on how to perform register accesses to Low Energy Peripherals.

**Note:** PCNTn_TOP and PCNTn_CNT are read-only registers. When writing to PCNTn_TOPB, make sure that the counter value, PCNTn CNT, can not exceed the value written to PCNTn TOPB within two clock cycles.

#### 16.3.6 Clock Sources

The pulse counter may be clocked from two possible clock sources: LFACLK or an external clock. The clock selection is configured by the PCNT0CLKSEL bit in the CMU_PCNTCTRL in the Clock Management Unit (CMU), 11. CMU - Clock Management Unit . The default clock source is the LFACLK.

This PCNT module may also use PCNTn_S0IN as an external clock to clock the counter (EXTCLKSINGLE mode) and to sample PCNTn_S1IN (EXTCLKQUAD mode). Setup, hold and max frequency constraints for PCNTn_S0IN and PCNTn_S1IN for these modes are specified in the device data sheet.

To use this module, the LE interface clock must be enabled in CMU_HFBUSCLKEN0, in addition to the module clock in CMU_PCNTCTRL.

**Note:** PCNT Clock Domain Reset, RSTEN, should be set when changing clock source for PCNT. If changing to an external clock source, the clock pin has to be enabled as input prior to de-asserting RSTEN. Changing clock source without asserting RSTEN results in undefined behaviour.

#### 16.3.7 Input Filter

An optional pulse width filter is available in OVSSINGLE and OVSQUAD modes, when LFACLK is selected as a clock source for the Pulse Counter in CMU 11. CMU - Clock Management Unit . The filter is enabled by writing 1 to the FILT bit in the PCNTn_CTRL register. When enabled, the high and low periods of PCNTn_S0IN and PCNTn_S1IN must be stable for a programmable number of consecutive clock cycles before the edge is passed to the edge detector. The filter length should be programmed in FILTLEN field of the PCNTn_OVSCFG register.

The filter length is given by Figure 16.12 PCNT Input Filter Length Equation on page 480:

Filter length = (FILTLEN + 5) LFACLK cycles

### Figure 16.12. PCNT Input Filter Length Equation

The maximum filter length configured is 260 LFACLK cycles.

In EXTCLKSINGLE and EXTCLKQUAD mode, there is no digital pulse width filter available.

### 16.3.8 Edge Polarity

The edge polarity can be set by configuring the EDGE bit in the PCNTn_CTRL register. When this bit is cleared, the pulse counter counts positive edges of PCNTn_S0IN input. When this bit is set, the pulse counter counts negative edges in OVSSINGLE mode. Also, when the EDGE bit is set in the OVSSINGLE and EXTCLKSINGLE modes, the PCNTn_S1IN input is inverted. In OVSQUAD 1X-4X modes the EDGE bit inverts both inputs.

Note: The EDGE bit in PCNTn_CTRL has no effect in EXTCLKQUAD mode.

### 16.3.9 PRS and PCNTn_S0IN,PCNTn_S1IN Inputs

It is possible to receive input from PRS on both PCNTn_S0IN (or PCNTn_S1IN) by setting S0PRSEN (or S1PRSEN) in PCNTn_IN-PUT. The PRS channel used can be selected using S0PRSSEL (or S1PRSSEL) in PCNTn_INPUT.

In the Oversampling quadrature decoder modes, the input frequency should be less than 8KHz to ensure correct functionality.

PCNT module generates three PRS outputs the TCC PRS output, the CNT OF/UF PRS output and the CNT DIR PRS output. The TCC PRS is generated on compare match of TCC event. The CNT OF/UF combined PRS is generated when the counter overflow or underflows. The CNT DIR PRS is a level PRS and indicates the current direction of count of counter CNT

Note: S0PRSEN,S1PRSEN,S0PRSSEL,S1PRSSEL should only be altered when RSTEN in PCNTn CTRL is set.

### 16.3.10 Interrupts

The interrupt generated by PCNT uses the PCNTn_INT interrupt vector. Software must read the PCNTn_IF register to determine which module interrupt that generated the vector invocation.

### 16.3.10.1 Underflow and Overflow Interrupts

The underflow interrupt flag (UF) is set when the counter counts down from 0. I.e. when the value of the counter is 0 and a new pulse is received. The PCNTn_CNT register is loaded with the PCNTn_TOP value after this event.

The overflow interrupt flag (OF) is set when the counter counts up from the PCNTn_TOP (reload) value. I.e. if PCNTn_CNT = PCNTn_TOP and a new pulse is received. The PCNTn_CNT register is loaded with the value 0 after this event.

## 16.3.10.2 Direction Change Interrupt

The PCNTn_PCNT module sets the DIRCNG interrupt flag (PCNTn_IF register) for EXTCLKQUAD and OVSQUAD1X-4X modes when the direction of the quadrature code changes. The behavior of this interrupt in the EXTCLKQUAD mode is illustrated by Figure 16.13 PCNT Direction Change Interrupt (DIRCNG) Generation on page 482.

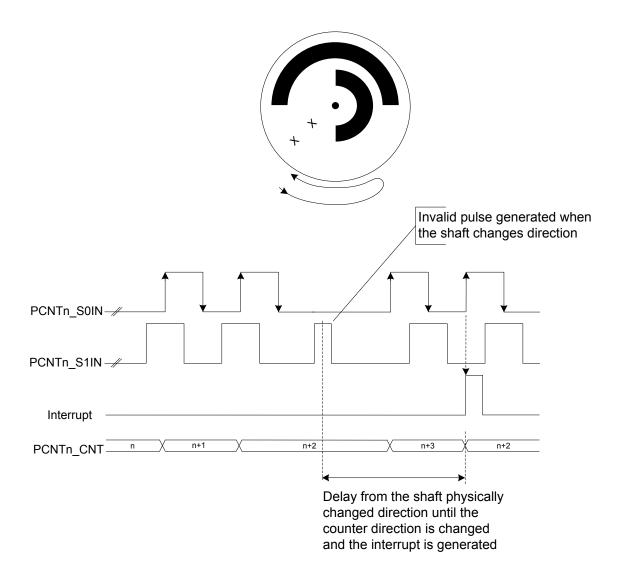

Figure 16.13. PCNT Direction Change Interrupt (DIRCNG) Generation

### 16.3.11 Cascading Pulse Counters

When two or more Pulse Counters are available, it is possible to cascade them. For example two 16-bit Pulse Counters can be cascaded to form a 32-bit pulse counter. This can be done with the help of the CNT UF/OF PRS and CNT DIR PRS ouputs. The figure Figure 16.14 PCNT Cascading to two 16-bit PCNT to form a 32-bit PCNT on page 483 illustrates this structure.

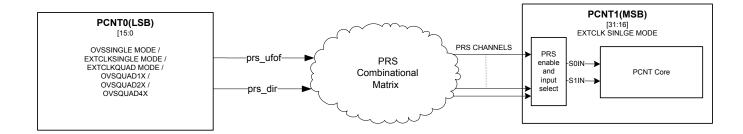

Figure 16.14. PCNT Cascading to two 16-bit PCNT to form a 32-bit PCNT

For cascading of Pulse Counters to work, the PCNT1 according to the figure Figure 16.14 PCNT Cascading to two 16-bit PCNT to form a 32-bit PCNT on page 483 should be programmed in EXTCLKSINGLE mode and its S0IN and S1IN inputs should be configured to prs_ufof and prs_dir of PCNT0 respectively. In addition to this, a strict programming sequence needs to be followed to ensure both PCNTs are in sync with each other.

- Configure PCNT0 registers. eg. PCNT0_INPUT,PCNT0_CTRL,PCNT0_OVSCFG etc.
- · Wait for PCNT0 SYCNBUSY to be cleared to ensure the registers are synchronized to the asynchronous clock domain.
- Hold PCNT0 in sw reset by setting PCNT0_CTRL_RSTEN.
- Configure PCNT1_CTRL to EXTCLKSINLE mode with S1CDIR and CNTDIR bit set. Configure INPUT to accept "prs_ufof" and
  "prs_dir" of PCNT0 on S0IN and S1IN respectively.
- Wait for PCNTn_SYCNBUSY to be cleared to ensure the registers are synchronized to the asynchronous clock domain. Use three PRS_SWPULSE on the S0IN prs channel to ensure this synchronization.
- Hold PCNT1 in sw reset by setting PCNT1 CTRL RSTEN.
- Clear PCNT1 CTRL RSTEN and synchronize it by asserting two PRS SWPULSE on the S0IN input.
- Finally clear PCNT0_CTRL_RSTEN and start counting.

**Note:** When RSTEN in PCNTn_CTRL is set, the TOP value in the Pulse Counter gets cleared. Therefore, in order to update the TOP value while RSTEN is set, assert TOPBHFEN bit in PCNTn_CTRL. This will update the TOP value with the TOPB value even without having to synchronize the TOPB value. This only works if TOPBHFEN and TOPB are configured while RSTEN in PCNTn_CTRL is set.

# 16.4 Register Map

## 17. I2C - Inter-Integrated Circuit Interface

### **Quick Facts**

### What?

The I²C interface allows communication on I²C-buses with the lowest energy consumption possible.

### Why?

I²C is a popular serial bus that enables communication with a number of external devices using only two I/O pins.

### How?

With the help of DMA, the  $I^2C$  interface allows  $I^2C$  communication with minimal CPU intervention. Address recognition is available in all energy modes (except EM4), allowing the MCU to wait for data on the  $I^2C$ -bus with sub- $\mu$ A current consumption.

### 17.1 Introduction

The  $I^2C$  module provides an interface between the MCU and a serial  $I^2C$ -bus. It is capable of acting as both a master and a slave and supports multi-master buses. Standard-mode, fast-mode and fast-mode plus speeds are supported, allowing transmission rates all the way from 10 kbit/s up to 1 Mbit/s. Slave arbitration and timeouts are also provided to allow implementation of an SMBus compliant system. The interface provided to software by the  $I^2C$  module allows precise control of the transmission process and highly automated transfers. Automatic recognition of slave addresses is provided in all energy modes (except EM4).

### 17.2 Features

- · True multi-master capability
- · Support for different bus speeds
  - Standard-mode (Sm) bit rate up to 100 kbit/s
  - · Fast-mode (Fm) bit rate up to 400 kbit/s
  - · Fast-mode Plus (Fm+) bit rate up to 1 Mbit/s
- Arbitration for both master and slave (allows SMBus ARP)
- · Clock synchronization and clock stretching
- · Hardware address recognition
  - · 7-bit masked address
  - · General call address
  - Active in all energy modes (except EM4)
- · 10-bit address support
- · Error handling
  - · Clock low timeout
  - · Clock high timeout
  - · Arbitration lost
  - · Bus error detection
- · Separate receive/ transmit 2-level buffers, with additional separate shift registers
- Full DMA support

## 17.3 Functional Description

An overview of the I2C module is shown in Figure 17.1 I2C Overview on page 502.

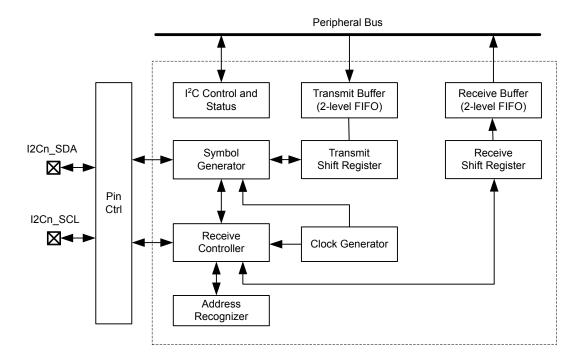

Figure 17.1. I2C Overview

### 17.3.1 I2C-Bus Overview

The I²C-bus uses two wires for communication; a serial data line (SDA) and a serial clock line (SCL) as shown in Figure 17.2 I2C-Bus Example on page 503. As a true multi-master bus it includes collision detection and arbitration to resolve situations where multiple masters transmit data at the same time without data loss.

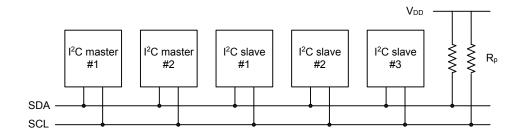

Figure 17.2. I2C-Bus Example

Each device on the bus is addressable by a unique address, and an I²C master can address all the devices on the bus, including other masters.

Both the bus lines are open-drain. The maximum value of the pull-up resistor can be calculated as a function of the maximal rise-time **tr** for the given bus speed, and the estimated bus capacitance **Cb** as shown in Figure 17.3 I2C Pull-up Resistor Equation on page 503.

$$Rp(max) = t_r / (0.8473 \times Cb)$$

Figure 17.3. I2C Pull-up Resistor Equation

The maximal rise times for 100 kHz, 400 kHz and 1 MHz I²C are 1 µs, 300 ns and 120 ns respectively.

#### Note:

- · The GPIO drive strength can be used to control slew rate.
- If V_{dd} drops below the voltage on SCL and SDA lines, the MCU could become back powered and pull the SCL and SDA lines low.

### 17.3.1.1 START and STOP Conditions

START and STOP conditions are used to initiate and stop transactions on the I²C-bus. All transactions on the bus begin with a START condition (S) and end with a STOP condition (P). As shown in Figure 17.4 I2C START and STOP Conditions on page 504, a START condition is generated by pulling the SDA line low while SCL is high, and a STOP condition is generated by pulling the SDA line high while SCL is high.

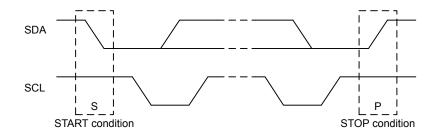

Figure 17.4. I2C START and STOP Conditions

The START and STOP conditions are easily identifiable bus events as they are the only conditions on the bus where a transition is allowed on SDA while SCL is high. During the actual data transmission, SDA is only allowed to change while SCL is low, and must be stable while SCL is high. One bit is transferred per clock pulse on the I²C-bus as shown in Figure 17.5 I2C Bit Transfer on I²C-Bus on page 504.

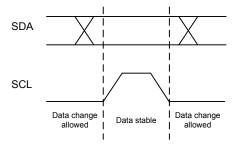

Figure 17.5. I2C Bit Transfer on I²C-Bus

#### 17.3.1.2 Bus Transfer

When a master wants to initiate a transfer on the bus, it waits until the bus is idle and transmits a START condition on the bus. The master then transmits the address of the slave it wishes to interact with and a single R/W bit telling whether it wishes to read from the slave (R/W bit set to 1) or write to the slave (R/W bit set to 0).

After the 7-bit address and the R/W bit, the master releases the bus, allowing the slave to acknowledge the request. During the next bit-period, the slave pulls SDA low (ACK) if it acknowledges the request, or keeps it high if it does not acknowledge it (NACK).

Following the address acknowledge, either the slave or master transmits data, depending on the value of the R/W bit. After every 8 bits (one byte) transmitted on the SDA line, the transmitter releases the line to allow the receiver to transmit an ACK or a NACK. Both the data and the address are transmitted with the most significant bit first.

The number of bytes in a bus transfer is unrestricted. The master ends the transmission after a (N)ACK by sending a STOP condition on the bus. After a STOP condition, any master wishing to initiate a transfer on the bus can try to gain control of it. If the current master wishes to make another transfer immediately after the current, it can start a new transfer directly by transmitting a repeated START condition (Sr) instead of a STOP followed by a START.

Examples of I²C transfers are shown in Figure 17.6 I2C Single Byte Write to Slave on page 505, Figure 17.7 I2C Double Byte Read from Slave on page 505, and Figure 17.8 I2C Single Byte Write, then Repeated Start and Single Byte Read on page 505. The identifiers used are:

- · ADDR Address
- · DATA Data
- · S Start bit
- · Sr Repeated start bit
- · P Stop bit
- W/R Read(1)/Write(0)
- A ACK
- N NACK

Figure 17.6. I2C Single Byte Write to Slave

Figure 17.7. I2C Double Byte Read from Slave

Figure 17.8. I2C Single Byte Write, then Repeated Start and Single Byte Read

#### 17.3.1.3 Addresses

 $I^2C$  supports both 7-bit and 10-bit addresses. When using 7-bit addresses, the first byte transmitted after the START-condition contains the address of the slave that the master wants to contact. In the 7-bit address space, several addresses are reserved. These addresses are summarized in Table 17.1 I2C Reserved  $I^2C$  Addresses on page 506, and include a General Call address which can be used to broadcast a message to all slaves on the  $I^2C$ -bus.

Table 17.1. I2C Reserved I²C Addresses

I ² C Address	R/W	Description
0000-000	0	General Call address
0000-000	1	START byte
0000-001	x	Reserved for the C-Bus format
0000-010	X	Reserved for a different bus format
0000-011	X	Reserved for future purposes
0000-1XX	x	Reserved for future purposes
1111-1XX	X	Reserved for future purposes
1111-0XX	X	10 Bit slave addressing mode

## 17.3.1.4 10-bit Addressing

To address a slave using a 10-bit address, two bytes are required to specify the address instead of one. The seven first bits of the first byte must then be 1111 0XX, where XX are the two most significant bits of the 10-bit address. As with 7-bit addresses, the eighth bit of the first byte determines whether the master wishes to read from or write to the slave. The second byte contains the eight least significant bits of the slave address.

When a slave receives a 10-bit address, it must acknowledge both the address bytes if they match the address of the slave.

When performing a master transmitter operation, the master transmits the two address bytes and then the remaining data, as shown in Figure 17.9 I2C Master Transmitter/Slave Receiver with 10-bit Address on page 506.

Figure 17.9. I2C Master Transmitter/Slave Receiver with 10-bit Address

When performing a master receiver operation however, the master first transmits the two address bytes in a master transmitter operation, then sends a repeated START followed by the first address byte and then receives data from the addressed slave. The slave addressed by the 10-bit address in the first two address bytes must remember that it was addressed, and respond with data if the address transmitted after the repeated start matches its own address. An example of this (with one byte transmitted) is shown in Figure 17.10 I2C Master Receiver/Slave Transmitter with 10-bit Address on page 506.

Figure 17.10. I2C Master Receiver/Slave Transmitter with 10-bit Address

### 17.3.1.5 Arbitration, Clock Synchronization, Clock Stretching

Arbitration and clock synchronization are features aimed at allowing multi-master buses. Arbitration occurs when two devices try to drive the bus at the same time. If one device drives it low, while the other drives it high, the one attempting to drive it high will not be able to do so due to the open-drain bus configuration. Both devices sample the bus, and the one that was unable to drive the bus in the desired direction detects the collision and backs off, letting the other device continue communication on the bus undisturbed.

Clock synchronization is a means of synchronizing the clock outputs from several masters driving the bus at once, and is a requirement for effective arbitration.

Slaves on the bus are allowed to force the clock output on the bus low in order to pause the communication on the bus and give themselves time to process data or perform any real-time tasks they might have. This is called clock stretching.

Arbitration is supported by the I²C module for both masters and slaves. Clock synchronization and clock stretching is also supported.

#### 17.3.2 Enable and Reset

The I²C is enabled by setting the EN bit in the I2Cn_CTRL register. Whenever this bit is cleared, the internal state of the I²C is reset, terminating any ongoing transfers.

**Note:** When enabling the I²C, the ABORT command or the Bus Idle Timeout feature must be applied prior to use even if the BUSY flag is not set.

### 17.3.3 Safely Disabling and Changing Slave Configuration

The I²C slave is partially asynchronous, and some precautions are necessary to always ensure a safe slave disable or slave configuration change. These measures should be taken, if (while the slave is enabled) the user cannot guarantee that an address match will not occur at the exact time of slave disable or slave configuration change.

Worst case consequences for an address match while disabling slave or changing configuration is that the slave may end up in an undefined state. To reset the slave back to a known state, the EN bit in I2Cn_CTRL must be reset. This should be done regardless of whether the slave is going to be re-enabled or not.

### 17.3.4 Clock Generation

The SCL signal generated by the I²C master determines the maximum transmission rate on the bus. The clock is generated as a division of the peripheral clock, and is given by the following equation:

$$f_{SCL} = f_{HFPERCLK}/(((N_{low} + N_{high}) \times (DIV + 1)) + 8),$$

## Figure 17.11. I2C Maximum Transmission Rate

 $N_{low}$  and  $N_{high}$  in combination with the synchronization cycles (discussed below) specify the number of prescaled clock cycles in the low and high periods of the clock signal respectively. The worst case low and high periods of the signal are:

$$T_{high} \ge ((N_{high}) \times (DIV + 1) + 4)/f_{HFPERCLK},$$

$$T_{low} \ge (N_{low} \times (DIV + 1) + 4)/f_{HFPERCLK}.$$

Figure 17.12. I2C High and Low Cycles Equations

In worst case,  $T_{high}$  and  $T_{low}$  can be 1  $f_{HFPERCLK}$  cycle longer than the number found by above equations due to synchronization uncertainity (i.e., if the synchronization takes 3  $f_{HFPERCLK}$  cycles instead of 2). Similarly, in the worst case the number 8 in the denominator in  $f_{SCL}$  equation can be 9 (if the synchronization cycles were 3 instead of 2 in  $T_{high}$  or  $T_{low}$ ) or 10 (if synchronization cycles were 3 in both  $T_{high}$  and  $T_{low}$ ). The values of  $N_{low}$  and  $N_{high}$  and thus the ratio between the high and low parts of the clock signal is controlled by CLHR in the I2Cn_CTRL register.

Note: DIV must be set to 1 during slave mode operation.

#### 17.3.5 Arbitration

Arbitration is enabled by default, but can be disabled by setting the ARBDIS bit in I2Cn_CTRL. When arbitration is enabled, the value on SDA is sensed every time the  $I^2C$  module attempts to change its value. If the sensed value is different than the value the  $I^2C$  module tried to output, it is interpreted as a simultaneous transmission by another device, and that the  $I^2C$  module has lost arbitration.

Whenever arbitration is lost, the ARBLOST interrupt flag in  $I2Cn_IF$  is set, any lines held are released, and the  $I^2C$  device goes idle. If an  $I^2C$  master loses arbitration during the transmission of an address, another master may be trying to address it. The master therefore receives the rest of the address, and if the address matches the slave address of the master, the master goes into either slave transmitter or slave receiver mode.

Note: Arbitration can be lost both when operating as a master and when operating as a slave.

#### 17.3.6 Buffers

The I2C peripheral includes separate receive and transmit buffers and shift registers.

#### 17.3.6.1 Transmit Buffer and Shift Register

The I²C transmitter has a 2-level FIFO transmit buffer and a transmit shift register as shown in Figure 17.1 I2C Overview on page 502. A byte is loaded into the transmit buffer by writing to I2Cn_TXDATA or 2 bytes can be loaded simultaneously in the transmit buffer by writing to I2Cn_TXDOUBLE. Figure 17.13 I2C Transmit Buffer Operation on page 508 shows the basics of the transmit buffer. When the transmit shift register is empty and ready for new data, the byte from the transmit buffer is then loaded into the shift register. The byte is then kept in the shift register until it is transmitted. When a byte has been transmitted, a new byte is loaded into the shift register (if available in the transmit buffer). If the transmit buffer is empty, then the shift register also remains empty. The TXC flag in I2Cn_STA-TUS and the TXC interrupt flags in I2Cn_IF are then set, signaling that the transmit shift register is out of data. TXC is cleared when new data becomes available, but the TXC interrupt flag must be cleared by software.

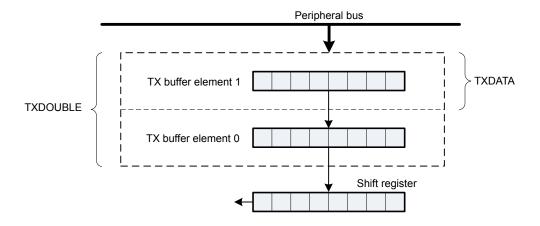

Figure 17.13. I2C Transmit Buffer Operation

The TXBL flags in the I2Cn_STATUS and I2Cn_IF are used to indicate the level of the transmit buffer. TXBIL in I2Cn_CTRL controls the level at which these flag bits are set. If TXBIL is cleared, the flags are set whenever the transmit buffer becomes empty (used when transmitting using I2Cn_TXDOUBLE). If TXBIL is set, the flags are set whenever the transmit buffer goes from full to half-empty or empty (used when transmitting with I2Cn_TXDATA). Both the TXBL status flag and the TXBL interrupt flag are cleared automatically when the condition becomes false.

If an attempt is made to write more bytes to the transmit buffer than the space available, the TXOF interrupt flag in I2Cn_IF is set, indicating the overflow. The data already in the buffer remains preserved, and no new data is written.

The transmit buffer and the transmit shift register can be cleared by setting command bit CLEARTX in I2Cn_CMD. This will prevent the I²C module from transmitting the data in the buffer and the shift register, and will make them available for new data. Any byte currently being transmitted will not be aborted. Transmission of this byte will be completed.

#### 17.3.6.2 Receive Buffer and Shift Register

The I²C receiver uses a 2-level FIFO receive buffer and a receive shift register as shown in Figure 17.14 I2C Receive Buffer Operation on page 509. When a byte has been fully received by the receive shift register, it is loaded into the receive buffer if there is room for it, making the shift register empty to receive another byte. Otherwise, the byte waits in the shift register until space becomes available in the buffer.

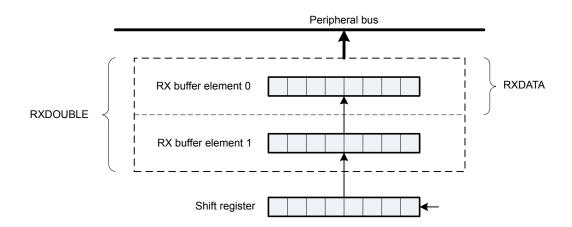

Figure 17.14. I2C Receive Buffer Operation

When a byte becomes available in the receive buffer, the RXDATAV in I2Cn_STATUS and RXDATAV interrupt flag in I2Cn_IF are set. When the buffer becomes full, RXFULL in the I2Cn_STATUS and I2Cn_IF are set. The status flags RXDATAV and RXFULL are automatically cleared by hardware when their condition is no longer true. This also goes for the RXDATAV interrupt flag, but the RXFULL interrupt flag must be cleared by software. When the RXFULL flag is set, notifying that the buffer is full, space is still available in the receive shift register for one more byte.

The data can be fetched from the buffer in two ways. I2Cn_RXDATA gives access to the received byte (if two bytes are received then the one received first is fetched first). I2Cn_RXDOUBLE makes it possible to read the two received bytes simultaneously. If an attempt is made to read more bytes from the buffer than available, the RXUF interrupt flag in I2Cn_IF is set to signal the underflow, and the data read from the buffer is undefined.

When using I2Cn_RXDOUBLE to pick data, AUTOACK in I2Cn_CTRL should be set to 1. This ensures that an ACK is automatically sent out after the first byte is received so that the reception of the next byte can begin. In order to stop receiving data bytes, a NACK must be sent out through the I2Cn_CMD register.

I2Cn_RXDATAP and I2Cn_RXDOUBLEP can be used to read data from the receive buffer without removing it from the buffer. The RXUF interrupt flag in I2Cn_IF will never be set as a result of reading from I2Cn_RXDATAP and I2Cn_RXDOUBLEP, but the data read through I2Cn_RXDATAP when the receive buffer is empty is still undefined.

Once a transaction is complete (STOP sent or received), the receive buffer needs to be flushed (all received data must be read) before starting a new transaction.

### 17.3.7 Master Operation

A bus transaction is initiated by transmitting a START condition (S) on the bus. This is done by setting the START bit in I2Cn_CMD. The command schedules a START condition, and makes the I²C module generate a start condition whenever the bus becomes free.

The I²C-bus is considered busy whenever another device on the bus transmits a START condition. Until a STOP condition is detected, the bus is owned by the master issuing the START condition. The bus is considered free when a STOP condition is transmitted on the bus. After a STOP is detected, all masters that have data to transmit send a START condition and begin transmitting data. Arbitration ensures that collisions are avoided.

When the START condition has been transmitted, the master must transmit a slave address (ADDR) with an R/W bit on the bus. If this address is available in the transmit buffer, the master transmits it immediately, but if the buffer is empty, the master holds the I²C-bus while waiting for software to write the address to the transmit buffer.

After the address has been transmitted, a sequence of bytes can be read from or written to the slave, depending on the value of the R/W bit (bit 0 in the address byte). If the bit was cleared, the master has entered a master transmitter role, where it now transmits data to the slave. If the bit was set, it has entered a master receiver role, where it now should receive data from the slave. In either case, an unlimited number of bytes can be transferred in one direction during the transmission.

At the end of the transmission, the master either transmits a repeated START condition (Sr) if it wishes to continue with another transfer, or transmits a STOP condition (P) if it wishes to release the bus. When operating in the master mode, HFPERCLK frequency must be higher than 2 MHz for Standard-mode, 9 MHz for Fast-mode, and 20 MHz for Fast-mode Plus.

#### 17.3.7.1 Master State Machine

The master state machine is shown in Figure 17.15 I2C Master State Machine on page 511. A master operation starts in the far left of the state machine, and follows the solid lines through the state machine, ending the operation or continuing with a new operation when arriving at the right side of the state machine.

Branches in the path through the state machine are the results of bus events and choices made by software, either directly or indirectly. The dotted lines show where I²C-specific interrupt flags are set along the path and the full-drawn circles show places where interaction may be required by software to let the transmission proceed.

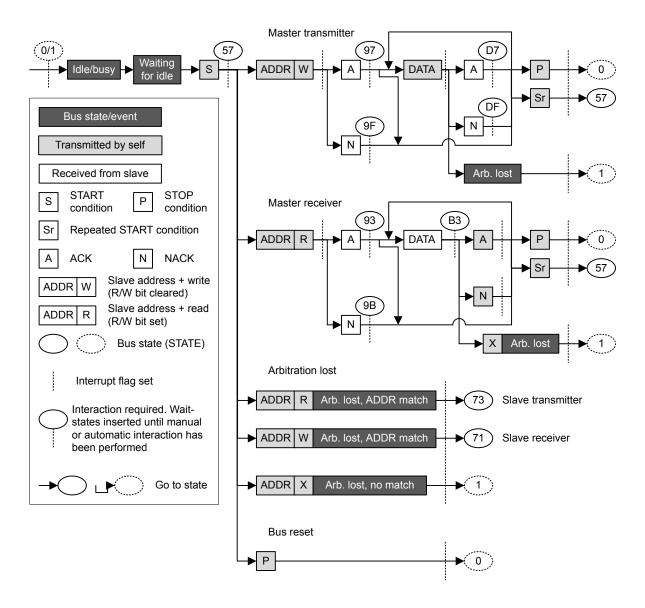

Figure 17.15. I2C Master State Machine

#### 17.3.7.2 Interactions

Whenever the  $I^2C$  module is waiting for interaction from software, it holds the bus clock SCL low, freezing all bus activities, and the BUSHOLD interrupt flag in  $I^2C$  module. This state can be read from the  $I^2C$  module. This state can be read from the  $I^2C$  module.

As an example, Table 17.3 I2C Master Transmitter on page 514 shows the different states the  $I^2C$  goes through when operating as a Master Transmitter, i.e., a master that transmits data to a slave. As seen in the table, when a start condition has been transmitted, a requirement is that there is an address and an R/W bit in the transmit buffer. If the transmit buffer is empty, then the BUSHOLD interrupt flag is set, and the bus is held until data becomes available in the buffer. While waiting for the address, I2Cn_STATE has a value 0x57, which can be used to identify exactly what the  $I^2C$  module is waiting for.

Note: The bus would never stop at state 0x57 if the address was available in the transmit buffer.

The different interactions used by the  $I^2C$  module are listed in Table 17.2 I2C Interactions in Prioritized Order on page 512 in a prioritized order. If the  $I^2C$  module is in such a state that multiple courses of action are possible, then the action chosen is the one that has the highest priority. For example, after sending out a START, if an address is present in the buffer and a STOP is also pending, then the  $I^2C$  will send out the STOP since it has the higher priority.

Table 17.2. I2C Interactions in Prioritized Order

Interaction	Priority	Software action	Automatically continues if
STOP*	1	Set the STOP command bit in I2Cn_CMD	PSTOP is set (STOP pending) in I2Cn_STATUS
ABORT	2	Set the ABORT command bit in I2Cn_CMD	Never, the transmission is aborted
CONT*	3	Set the CONT command bit in I2Cn_CMD	PCONT is set in I2Cn_STATUS (CONT pending)
NACK*	4	Set the NACK command bit in I2Cn_CMD	PNACK is set in I2Cn_STATUS (NACK pending)
ACK*	5	Set the ACK command bit in I2Cn_CMD	AUTOACK is set in I2Cn_CTRL or PACK is set in I2Cn_STA-TUS (ACK pending)
ADDR+W -> TXDATA	6	Write an address to the transmit buffer with the R/W bit set	Address is available in transmit buffer with R/W bit set
ADDR+R -> TXDATA	7	Write an address to the transmit buffer with the R/W bit cleared	Address is available in transmit buffer with R/W bit cleared
START*	8	Set the START command bit in I2Cn_CMD	PSTART is set in I2Cn_STA- TUS (START pending)
TXDATA/ TXDOUBLE	9	Write data to the transmit buffer	Data is available in transmit buffer
RXDATA/ RXDOUBLE	10	Read data from receive buffer	Space is available in receive buffer
None	11	No interaction is required	

The commands marked with a * in Table 17.2 I2C Interactions in Prioritized Order on page 512 can be issued before an interaction is required. When such a command is issued before it can be used/consumed by the I²C module, the command is set in a pending state, which can be read from the STATUS register. A pending START command can for instance be identified by PSTART having a high value.

Whenever the I²C module requires an interaction, it checks the pending commands. If one or a combination of these can fulfill an interaction, they are consumed by the module and the transmission continues without setting the BUSHOLD interrupt flag in I2Cn_IF to get an interaction from software. The pending status of a command goes low when it is consumed.

When several interactions are possible from a set of pending commands, the interaction with the highest priority, i.e., the interaction closest to the top of Table 17.2 I2C Interactions in Prioritized Order on page 512 is applied to the bus.

Pending commands can be cleared by setting the CLEARPC command bit in I2Cn_CMD.

#### 17.3.7.3 Automatic ACK Interaction

When receiving addresses and data, an ACK command in I2Cn_CMD is normally required after each received byte. When AUTOACK is set in I2Cn_CTRL, an ACK is always pending, and the ACK-pending bit PACK in I2Cn_STATUS is thus always set, even after an ACK has been consumed. This is used when data is picked using I2Cn_RXDOUBLE and can also be used with I2Cn_RXDATA in order to reduce the amount of software interaction required during a transfer.

#### 17.3.7.4 Reset State

After a reset, the state of the  $I^2C$ -bus is unknown. To avoid interrupting transfers on the  $I^2C$ -bus after a reset of the  $I^2C$  module or the entire MCU, the  $I^2C$ -bus is assumed to be busy when coming out of a reset, and the BUSY flag in  $I^2C$ -bus is thus set. To be able to carry through master operations on the  $I^2C$ -bus, the bus must be idle.

The bus goes idle when a STOP condition is detected on the bus, but on buses with little activity, the time before the  $I^2C$  module detects that the bus is idle can be significant. There are two ways of assuring that the  $I^2C$  module gets out of the busy state.

- Use the ABORT command in I2Cn_CMD. When the ABORT command is issued, the I²C module is instructed that the bus is idle. The I²C module can then initiate master operations.
- Use the Bus Idle Timeout. When SCL has been high for a long period of time, it is very likely that the bus is idle. Set BITO in I2Cn_CTRL to an appropriate timeout period and set GIBITO in I2Cn_CTRL. If activity has not been detected on the bus within the timeout period, the bus is then automatically assumed idle, and master operations can be initiated.

**Note:** If operating in slave mode, the above approach is not necessary.

#### 17.3.7.5 Master Transmitter

To transmit data to a slave, the master must operate as a master transmitter. Table 17.3 I2C Master Transmitter on page 514 shows the states the I²C module goes through while acting as a master transmitter. Every state where an interaction is required has the possible interactions listed, along with the result of the interactions. The table also shows which interrupt flags are set in the different states. The interrupt flags enclosed in parenthesis may be set. If the BUSHOLD interrupt in I2Cn_IF is set, the module is waiting for an interaction, and the bus is frozen. The value of I2Cn_STATE will be equal to the values given in the table when the BUSHOLD interrupt flag is set, and can be used to determine which interaction is required to make the transmission continue.

The interrupt flag START in I2Cn IF is set when the I2C module transmits the START.

A master operation is started by issuing a START command by setting START in I2Cn_CMD. ADDR+W, i.e., the address of the slave + the R/W bit is then required by the  $I^2C$  module. If this is not available in the transmit buffer, then the bus is held and the BUSHOLD interrupt flag is set. The value of I2Cn_STATE will then be 0x57. As seen in the table, the  $I^2C$  module also stops in this state if the address is not available after a repeated start condition.

To continue, write a byte to I2Cn_TXDATA with the address of the slave in the 7 most significant bits and the least significant bit cleared (ADDR+W). This address will then be transmitted, and the slave will reply with an ACK or a NACK. If no slave replies to the address, the response will also be NACK. If the address was acknowledged, the master now has four choices. It can send data by placing it in I2Cn_TXDATA/ I2Cn_TXDOUBLE (the master should check the TXBL interrupt flag before writing to the transmit buffer), this data is then transmitted. The master can also stop the transmission by sending a STOP, it can send a repeated start by sending START, or it can send a STOP and then a START as soon as possible. If the master wishes to make another transfer immediately after the current, the preferred way is to start a new transfer directly by transmitting a repeated START instead of a STOP followed by a START. This is so because if a STOP is sent out, then any master wishing to initiate a transfer on the bus can try to gain control of it.

If a NACK was received, the master has to issue a CONT command in addition to providing data in order to continue transmission. This is not standard I²C, but is provided for flexibility. The rest of the options are similar to when an ACK was received.

If a new byte was transmitted, an ACK or NACK is received after the transmission of the byte, and the master has the same options as for when the address was sent.

The master may lose arbitration at any time during transmission. In this case, the ARBLOST interrupt flag in I2Cn_IF is set. If the arbitration was lost during the transfer of an address, and SLAVE in I2Cn_CTRL is set, the master then checks which address was transmitted. If it was the address of the master, then the master goes to slave mode.

After a master has transmitted a START and won any arbitration, it owns the bus until it transmits a STOP. After a STOP, the bus is released, and arbitration decides which bus master gains the bus next. The MSTOP interrupt flag in I2Cn_IF is set when a STOP condition is transmitted by the master.

Table 17.3. I2C Master Transmitter

I2Cn_STATE	Description	I2Cn_IF	Required in- teraction	Response
0x57	Start transmitted	START interrupt flag (BUSHOLD interrupt	ADDR+W -> TXDATA	ADDR+W will be sent
		flag)	STOP	STOP will be sent and bus released.
			STOP + START	STOP will be sent and bus released. Then a START will be sent when bus becomes idle.
0x57	mitted	START interrupt flag (BUSHOLD interrupt flag)	ADDR+W -> TXDATA	ADDR+W will be sent
			STOP	STOP will be sent and bus released.
			STOP + START	STOP will be sent and bus released. Then a START will be sent when bus becomes idle.
-	ADDR+W transmitted	TXBL interrupt flag (TXC interrupt flag)	None	

I2Cn_STATE	Description	I2Cn_IF	Required in- teraction	Response
	ADDR+W transmitted,	ACK interrupt flag	TXDATA	DATA will be sent
	ACK received	(BUSHOLD interrupt flag)	STOP	STOP will be sent. Bus will be released
			START	Repeated start condition will be sent
			STOP + START	STOP will be sent and the bus released. Then a START will be sent when the bus becomes idle
0x9F	ADDR+W transmit- ted,NACK received	NACK (BUSHOLD interrupt flag)	CONT + TXDATA	DATA will be sent
			STOP	STOP will be sent. Bus will be released
			START	Repeated start condition will be sent
			STOP + START	STOP will be sent and the bus released. Then a START will be sent when the bus becomes idle
-	Data transmitted	TXBL interrupt flag (TXC interrupt flag)	None	
0xD7	Data transmitted,ACK	ACK interrupt flag (BUSHOLD interrupt flag)	TXDATA	DATA will be sent
	received		STOP	STOP will be sent. Bus will be released
			START	Repeated start condition will be sent
			STOP + START	STOP will be sent and the bus released. Then a START will be sent when the bus becomes idle
0xDF	Data transmitted,NACK received	NACK(BUSHOLD interrupt flag)	CONT + TXDATA	DATA will be sent
			STOP	STOP will be sent. Bus will be released
			START	Repeated start condition will be sent
			STOP + START	STOP will be sent and the bus released. Then a START will be sent when the bus becomes idle
-	Stop transmitted	MSTOP interrupt flag	None	
			START	START will be sent when bus becomes idle
-	Arbitration lost	ARBLOST interrupt flag	None	
			START	START will be sent when bus becomes idle

#### 17.3.7.6 Master Receiver

To receive data from a slave, the master must operate as a master receiver, see Table 17.4 I2C Master Receiver on page 516. This is done by transmitting ADDR+R as the address byte instead of ADDR+W, which is transmitted to become a master transmitter. The address byte loaded into the data register thus has to contain the 7-bit slave address in the 7 most significant bits of the byte, and have the least significant bit set.

When the address has been transmitted, the master receives an ACK or a NACK. If an ACK is received, the ACK interrupt flag in I2Cn_IF is set, and if space is available in the receive shift register, reception of a byte from the slave begins. If the receive buffer and shift register is full however, the bus is held until data is read from the receive buffer or another interaction is made. Note that the STOP and START interactions have a higher priority than the data-available interaction, so if a STOP or START command is pending, the highest priority interaction will be performed, and data will not be received from the slave.

If a NACK was received, the CONT command in I2Cn_CMD has to be issued in order to continue receiving data, even if there is space available in the receive buffer and/or shift register.

After a data byte has been received the master must ACK or NACK the received byte. If an ACK is pending or AUTOACK in I2Cn_CTRL is set, an ACK is sent automatically and reception continues if space is available in the receive buffer.

If a NACK is sent, the CONT command must be used in order to continue transmission. If an ACK or NACK is issued along with a START or STOP or both, then the ACK/NACK is transmitted and the reception is ended. If START in I2Cn_CMD is set alone, a repeated start condition is transmitted after the ACK/NACK. If STOP in I2Cn_CMD is set, a stop condition is sent regardless of whether START is set. If START is set in this case, it is set as pending.

As when operating as a master transmitter, arbitration can be lost as a master receiver. When this happens the ARBLOST interrupt flag in I2Cn_IF is set, and the master has a possibility of being selected as a slave given the correct conditions.

Table 17.4. I2C Master Receiver

I2Cn_STATE	Description	I2Cn_IF	Required in- teraction	Response
0x57	START transmitted	START interrupt flag (BUSHOLD interrupt	ADDR+R -> TXDATA	ADDR+R will be sent
		flag)	STOP	STOP will be sent and bus released.
			STOP + START	STOP will be sent and bus released. Then a START will be sent when bus becomes idle.
0x57	Repeated START transmitted	START interrupt flag(BUSHOLD inter-	ADDR+R -> TXDATA	ADDR+R will be sent
		rupt flag)	STOP	STOP will be sent and bus released.
			STOP + START	STOP will be sent and bus released. Then a START will be sent when bus becomes idle.
-	ADDR+R transmitted	TXBL interrupt flag (TXC interrupt flag)	None	
0x93	ADDR+R transmitted,	ACK interrupt flag(BUS-	RXDATA	Start receiving
	ACK received	,	STOP	STOP will be sent and the bus released
			START	Repeated START will be sent
			STOP + START	STOP will be sent and the bus released. Then a START will be sent when the bus becomes idle
0x9B	ADDR+R transmit- ted,NACK received	NACK(BUSHOLD)	CONT + RXDATA	Continue, start receiving
			STOP	STOP will be sent and the bus released
			START	Repeated START will be sent
			STOP + START	STOP will be sent and the bus released. Then a START will be sent when the bus becomes idle

I2Cn_STATE	Description	I2Cn_IF	Required in- teraction	Response						
0xB3	Data received	RXDATA interrupt flag(BUSHOLD inter-	ACK + RXDA- TA	ACK will be transmitted, reception continues						
	rupt flag)	NACK + CONT + RXDATA	NACK will be transmitted, reception continues							
			ACK/NACK + STOP	ACK/NACK will be sent and the bus will be released.						
									ACK/NACK + START	ACK/NACK will be sent, and then a repeated start condition.
			ACK/NACK + STOP + START	ACK/NACK will be sent and the bus will be released. Then a START will be sent when the bus becomes idle						
-	Stop received MSTOP interrupt flag	MSTOP interrupt flag	None							
			START	START will be sent when bus becomes idle						
-	Arbitration lost ARBLOST interrupt flag	ARBLOST interrupt flag	None							
			START	START will be sent when bus becomes idle						

#### 17.3.8 Bus States

The I2Cn_STATE register can be used to determine which state the  $I^2C$  module and the  $I^2C$  bus are in at a given time. The register consists of the STATE bit-field, which shows which state the  $I^2C$  module is at in any ongoing transmission, and a set of single-bits, which reveal the transmission mode, whether the bus is busy or idle, and whether the bus is held by this  $I^2C$  module waiting for a software response.

The possible values of the STATE field are summarized in Table 17.5 I2C STATE Values on page 518. When this field is cleared, the I²C module is not a part of any ongoing transmission. The remaining status bits in the I2Cn_STATE register are listed in Table 17.6 I2C Transmission Status on page 518.

Table 17.5. I2C STATE Values

Mode	Value	Description	
IDLE	0	No transmission is being performed by this module.	
WAIT	1	Waiting for idle. Will send a start condition as soon as the bus is idle.	
START	2	Start being transmitted	
ADDR	3	Address being transmitted or has been received	
ADDRACK	4	Address ACK/NACK being transmitted or received	
DATA	5	Data being transmitted or received	
DATAACK	6	Data ACK/NACK being transmitted or received	

Table 17.6. I2C Transmission Status

Bit	Description	
BUSY	Set whenever there is activity on the bus. Whether or not this module is responsible for the activity cannot be determined by this byte.	
MASTER	Set when operating as a master. Cleared at all other times.	
TRANSMITTER	Set when operating as a transmitter; either a master transmitter or a slave transmitter. Cleared at all other times	
BUSHOLD	Set when the bus is held by this I ² C module because an action is required by software.	
NACK	Only valid when bus is held and STATE is ADDRACK or DATAACK. In that case it is set if a NACK was received. In all other cases, the bit is cleared.	

**Note:** I2Cn_STATE reflects the internal state of the  $I^2$ C module, and therefore only held constant as long as the bus is held, i.e., as long as BUSHOLD in I2Cn_STATUS is set.

## 17.3.9 Slave Operation

The I²C module operates in master mode by default. To enable slave operation, i.e., to allow the device to be addressed as an I²C slave, the SLAVE bit in I2Cn_CTRL must be set. In this case the I²C module operates in a mixed mode, both capable of starting transmissions as a master, and being addressed as a slave. When operating in the slave mode, HFPERCLK frequency must be higher than 2 MHz for Standard-mode, 5 MHz for Fast-mode, and 14 MHz for Fast-mode Plus.

## 17.3.9.1 Slave State Machine

The slave state machine is shown in Figure 17.16 I2C Slave State Machine on page 519. The dotted lines show where I²C-specific interrupt flags are set. The full-drawn circles show places where interaction may be required by software to let the transmission proceed.

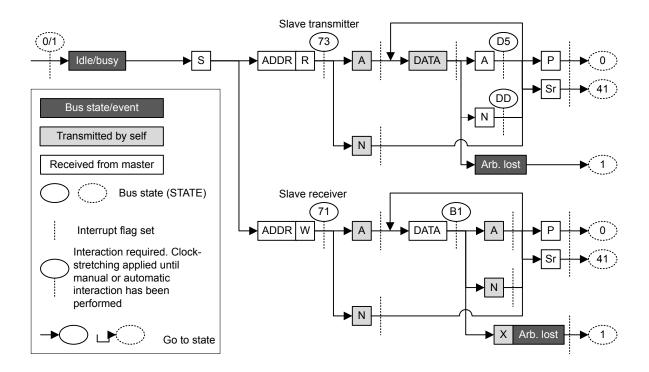

Figure 17.16. I2C Slave State Machine

## 17.3.9.2 Address Recognition

The I²C module provides automatic address recognition for 7-bit addresses. 10-bit address recognition is not fully automatic, but can be assisted by the 7-bit address comparator as shown in 17.3.11 Using 10-bit Addresses. Address recognition is supported in all energy modes (except EM4).

The slave address, i.e., the address which the I²C module should be addressed with, is defined in the I2Cn_SADDR register. In addition to the address, a mask must be specified, telling the address comparator which bits of an incoming address to compare with the address defined in I2Cn_SADDR. The mask is defined in I2Cn_SADDRMASK, and for every zero in the mask, the corresponding bit in the slave address is treated as a don't-care, i.e., the 0-masked bits are ignored.

An incoming address that fails address recognition is automatically replied to with a NACK. Since only the bits defined by the mask are checked, a mask with a value 0x00 will result in all addresses being accepted. A mask with a value 0x7F will only match the exact address defined in I2Cn_SADDR, while a mask 0x70 will match all addresses where the three most significant bits in I2Cn_SADDR and the incoming address are equal.

If GCAMEN in I2Cn_CTRL is not set, the start-byte, i.e., the general call address with the R/W bit set is ignored unless it is included in the defined slave address and and the address mask.

When an address is accepted by the address comparator, the decision of whether to ACK or NACK the address is passed to software.

#### 17.3.9.3 Slave Transmitter

When SLAVE in I2Cn_CTRL is set, the RSTART interrupt flag in I2Cn_IF will be set when repeated START conditions are detected. After a START or repeated START condition, the bus master will transmit an address along with an R/W bit. If there is no room in the receive shift register for the address, the bus will be held by the slave until room is available in the shift register. Transmission then continues and the address is loaded into the shift register. If this address does not pass address recognition, it is automatically NACK'ed by the slave, and the slave goes to an idle state. The address byte is in this case discarded, making the shift register ready for a new address. It is not loaded into the receive buffer.

If the address was accepted and the R/W bit was set (R), indicating that the master wishes to read from the slave, the slave now goes into the slave transmitter mode. Software interaction is now required to decide whether the slave wants to acknowledge the request or not. The accepted address byte is loaded into the receive buffer like a regular data byte. If no valid interaction is pending, the bus is held until the slave responds with a command. The slave can reject the request with a single NACK command.

The slave will in that case go to an idle state, and wait for the next start condition. To continue the transmission, the slave must make sure data is loaded into the transmit buffer and send an ACK. The loaded data will then be transmitted to the master, and an ACK or NACK will be received from the master.

Data transmission can also continue after a NACK if a CONT command is issued along with the NACK. This is not standard I²C however.

If the master responds with an ACK, it may expect another byte of data, and data should be made available in the transmit buffer. If data is not available, the bus is held until data is available.

If the response is a NACK however, this is an indication of that the master has received enough bytes and wishes to end the transmission. The slave now automatically goes idle, unless CONT in I2Cn_CMD is set and data is available for transmission. The latter is not standard I²C.

The master ends the transmission by sending a STOP or a repeated START. The SSTOP interrupt flag in I2Cn_IF is set when the master transmits a STOP condition. If the transmission is ended with a repeated START, then the SSTOP interrupt flag is not set.

**Note:** The SSTOP interrupt flag in I2Cn_IF will be set regardless of whether the slave is participating in the transmission or not, as long as SLAVE in I2Cn_CTRL is set and a STOP condition is detected.

If arbitration is lost at any time during transmission, the ARBLOST interrupt flag in I2Cn_IF is set, the bus is released and the slave goes idle.

See Table 17.7 I2C Slave Transmitter on page 520 for more information.

Table 17.7. I2C Slave Transmitter

I2Cn_STATE	Description	I2Cn_IF	Required in- teraction	Response
0x41	Repeated START received	RSTART interrupt flag (BUSHOLD interrupt flag)	RXDATA	Receive and compare address
0x75	ADDR + R received	ADDR interrupt flag	ACK + TXDA- TA	ACK will be sent, then DATA
		RXDATA interrupt flag	NACK	NACK will be sent, slave goes idle
		(BUSHOLD interrupt flag)	NACK + CONT + TXDATA	NACK will be sent, then DATA.
-	Data transmitted	TXBL interrupt flag (TXC interrupt flag)	None	
0xD5	Data transmitted, ACK received	ACK interrupt flag (BUSHOLD interrupt flag)	TXDATA	DATA will be transmitted
0xDD	Data transmitted, NACK	NACK interrupt flag	None	The slave goes idle
	received	(BUSHOLD interrupt flag)	CONT + TXDATA	DATA will be transmitted

I2Cn_STATE	Description	I2Cn_IF	Required in- teraction	Response
-	Stop received	SSTOP interrupt flag	None	The slave goes idle
			START	START will be sent when bus becomes idle
-	Arbitration lost	ARBLOST interrupt flag	None	The slave goes idle
			START	START will be sent when the bus becomes idle

#### 17.3.9.4 Slave Receiver

A slave receiver operation is started in the same way as a slave transmitter operation, with the exception that the address transmitted by the master has the R/W bit cleared (W), indicating that the master wishes to write to the slave. The slave then goes into slave receiver mode.

To receive data from the master, the slave should respond to the address with an ACK and make sure space is available in the receive buffer. Transmission will then continue, and the slave will receive a byte from the master.

If a NACK is sent without a CONT, the transmission is ended for the slave, and it goes idle. If the slave issues both the NACK and CONT commands and has space available in the receive buffer, it will be open for continuing reception from the master.

When a byte has been received from the master, the slave must ACK or NACK the byte. The responses here are the same as for the reception of the address byte.

The master ends the transmission by sending a STOP or a repeated START. The SSTOP interrupt flag is set when the master transmits a STOP condition. If the transmission is ended with a repeated START, then the SSTOP interrupt flag in I2Cn IF is not set.

**Note:** The SSTOP interrupt flag in I2Cn_IF will be set regardless of whether the slave is participating in the transmission or not, as long as SLAVE in I2Cn_CTRL is set and a STOP condition is detected

If arbitration is lost at any time during transmission, the ARBLOST interrupt flag in I2Cn_IF is set, the bus is released and the slave goes idle.

See Table 17.8 I2C - Slave Receiver on page 522 for more information.

Table 17.8. I2C - Slave Receiver

I2Cn_STATE	Description	I2Cn_IF	Required in- teraction	Response
-	Repeated START received	RSTART interrupt flag (BUSHOLD interrupt flag)	RXDATA	Receive and compare address
0x71	ADDR + W received	ADDR interrupt flag RXDATA interrupt flag	ACK + RXDATA	ACK will be sent and data will be received
		(BUSHOLD interrupt flag)	NACK	NACK will be sent, slave goes idle
			NACK + CONT + RXDATA	NACK will be sent and DATA will be received.
0xB1	xB1 Data received	RXDATA interrupt flag (BUSHOLD interrupt flag)	ACK + RXDATA	ACK will be sent and data will be received
			NACK	NACK will be sent and slave will go idle
			NACK + CONT + RXDATA	NACK will be sent and data will be received
-	Stop received	SSTOP interrupt flag	None	The slave goes idle
			START	START will be sent when bus becomes idle
-	Arbitration lost	ARBLOST interrupt flag	None	The slave goes idle
			START	START will be sent when the bus becomes idle

### 17.3.10 Transfer Automation

The I²C can be set up to complete transfers with a minimal amount of interaction.

#### 17.3.10.1 DMA

DMA can be used to automatically load data into the transmit buffer and load data out from the receive buffer. When using DMA, software is thus relieved of moving data to and from memory after each transferred byte.

#### 17.3.10.2 Automatic ACK

When AUTOACK in I2Cn_CTRL is set, an ACK is sent automatically whenever an ACK interaction is possible and no higher priority interactions are pending.

#### 17.3.10.3 Automatic STOP

A STOP can be generated automatically on two conditions. These apply only to the master transmitter.

If AUTOSN in I2Cn_CTRL is set, the I²C module ends a transmission by transmitting a STOP condition when operating as a master transmitter and a NACK is received.

If AUTOSE in I2Cn_CTRL is set, the I²C module always ends a transmission when there is no more data in the transmit buffer. If data has been transmitted on the bus, the transmission is ended after the (N)ACK has been received by the slave. If a START is sent when no data is available in the transmit buffer and AUTOSE is set, then the STOP condition is sent immediately following the START. Software must thus make sure data is available in the transmit buffer before the START condition has been fully transmitted if data is to be transferred.

## 17.3.11 Using 10-bit Addresses

When using 10-bit addresses in slave mode, set the I2Cn_SADDR register to 1111 0XX where XX are the two most significant bits of the 10-bit address, and set I2Cn_SADDRMASK to 0xFF. Address matches will now be given on all 10-bit addresses where the two most significant bits are correct.

When receiving an address match, the slave must acknowledge the address and receive the first data byte. This byte contains the second part of the 10-bit address. If it matches the address of the slave, the slave should ACK the byte to continue the transmission, and if it does not match, the slave should NACK it.

When the master is operating as a master transmitter, the data bytes will follow after the second address byte. When the master is operating as a master receiver however, a repeated START condition is sent after the second address byte. The address sent after this repeated START is equal to the first of the address bytes transmitted previously, but now with the R/W byte set, and only the slave that found a match on the entire 10-bit address in the previous message should ACK this address. The repeated start should take the master into a master receiver mode, and after the single address byte sent this time around, the slave begins transmission to the master.

### 17.3.12 Error Handling

**Note:** The setting of GCAMEN and SLAVE fields in the I2Cn_CTRL register and the registers I2Cn_SADDR and I2Cn_ROUTELOC0 are considered static. This means that these need to be set before an I²C transaction starts and need to stay stable during the entire transaction.

### 17.3.12.1 ABORT Command

Some bus errors may require software intervention to be resolved. The I²C module provides an ABORT command, which can be set in I2Cn CMD, to help resolve bus errors.

When the bus for some reason is locked up and the  $I^2C$  module is in the middle of a transmission it cannot get out of, or for some other reason the  $I^2C$  wants to abort a transmission, the ABORT command can be used.

Setting the ABORT command will make the I²C module discard any data currently being transmitted or received, release the SDA and SCL lines and go to an idle mode. ABORT effectively makes the I²C module forget about any ongoing transfers.

### 17.3.12.2 Bus Reset

A bus reset can be performed by setting the START and STOP commands in I2Cn_CMD while the transmit buffer is empty. A START condition will then be transmitted, immediately followed by a STOP condition. A bus reset can also be performed by transmitting a START command with the transmit buffer empty and AUTOSE set.

#### 17.3.12.3 I2C-Bus Errors

An I²C-bus error occurs when a START or STOP condition is misplaced, which happens when the value on SDA changes while SCL is high during bit-transmission on the I²C-bus. If the I²C module is part of the current transmission when a bus error occurs, any data currently being transmitted or received is discarded, SDA and SCL are released, the BUSERR interrupt flag in I2Cn_IF is set to indicate the error, and the module automatically takes a course of action as defined in Table 17.9 I2C Bus Error Response on page 524.

### Table 17.9. I2C Bus Error Response

	Misplaced START	Misplaced STOP
In a master/slave operation	Treated as START. Receive address.	Go idle. Perform any pending actions.

### 17.3.12.4 Bus Lockup

A lockup occurs when a master or slave on the I²C-bus has locked the SDA or SCL at a low value, preventing other devices from putting high values on the bus, and thus making communication on the bus impossible.

Many slave-only devices operating on an I²C-bus are not capable of driving SCL low, but in the rare case that SCL is stuck LOW, the advice is to apply a hardware reset signal to the slaves on the bus. If this does not work, cycle the power to the devices in order to make them release SCL.

When SDA is stuck low and SCL is free, a master should send 9 clock pulses on SCL while tristating the SDA. This procedure is performed in the GPIO module after clearing the I2C_ROUTE register and disabling the I2C module. The device that held the bus low should release it sometime within those 9 clocks. If not, use the same approach as for when SCL is stuck, resetting and possibly cycling power to the slaves.

Lockup of SDA can be detected by keeping count of the number of continuous arbitration losses during address transmission. If arbitration is also lost during the transmission of a general call address, i.e., during the transmission of the STOP condition, which should never happen during normal operation, this is a good indication of SDA lockup.

Detection of SCL lockups can be done using the timeout functionality defined in 17.3.12.6 Clock Low Timeout

#### 17.3.12.5 Bus Idle Timeout

When SCL has been high for a significant amount of time, this is a good indication of that the bus is idle. On an SMBus system, the bus is only allowed to be in this state for a maximum of 50 µs before the bus is considered idle.

The bus idle timeout BITO in I2Cn_CTRL can be used to detect situations where the bus goes idle in the middle of a transmission. The timeout can be configured in BITO, and when the bus has been idle for the given amount of time, the BITO interrupt flag in I2Cn_IF is set. The bus can also be set idle automatically on a bus idle timeout. This is enabled by setting GIBITO in I2Cn_CTRL.

When the bus idle timer times out, it wraps around and continues counting as long as its condition is true. If the bus is not set idle using GIBITO or the ABORT command in I2Cn CMD, this will result in periodic timeouts.

Note: This timeout will be generated even if SDA is held low.

The bus idle timeout is active as long as the bus is busy, i.e., BUSY in I2Cn_STATUS is set. The timeout can be used to get the I²C module out of the busy-state it enters when reset, see 17.3.7.4 Reset State.

### 17.3.12.6 Clock Low Timeout

The clock timeout, which can be configured in CLTO in I2Cn_CTRL, starts counting whenever SCL goes low, and times out if SCL does not go high within the configured timeout. A clock low timeout results in CLTOIF in I2Cn_IF being set, allowing software to take action.

When the timer times out, it wraps around and continues counting as long as SCL is low. An SCL lockup will thus result in periodic clock low timeouts as long as SCL is low.

#### 17.3.12.7 Clock Low Error

The I²C module can continue transmission in parallel with another device for the entire transaction, as long as the two communications are identical. A case may arise when (before an arbitration has been decided upon) the I²C module decides to send out a repeated START or a STOP condition while the other device is still sending data. In the I²C protocol specifications, such a combination results in an undefined condition. The I²C deals with this by generating a clock low error. This means that if the I²C is transmitting a repeated START or a STOP condition and another device (another master or a misbehaving slave) pulls SCL low before the I²C sends out the START/STOP condition on SDA, a clock low error is generated. The CLERR interrupt flag is then set in the I²C device goes to idle.

#### 17.3.13 DMA Support

The I²C module has full DMA support. A request for the DMA controller to write to the I²C transmit buffer can come from TXBL (transmit buffer has room for more data). The DMA controller can write to the transmit buffer using the I2Cn_TXDATA or the I2Cn_TXDOUBLE register. In order to write to the I2Cn_TXDOUBLE register (i.e., transferring 2 bytes simultaneously to the transmit buffer using the DMA), DMA_USEBURSTS needs to be set to 1 for the selected DMA channel. This ensures that the transfer is made to the transmit buffer only when both buffer elements are empty. For performing a DMA write to the I2Cn_TXDATA register, DMA_USEBURSTC needs to be set to 1 for the selected DMA channel. This ensures that a DMA transfer is made even when the transmit buffer is half-empty.

A request for the DMA controller to read from the I²C receive buffer can come from RXDATAV (data available in the receive buffer). To receive from I2Cn_RXDOUBLE (i.e., receive only when both buffer elements are full), DMA_USEBURSTS needs to be set to 1 for the selected DMA channel. In order to receive from I2Cn_RXDATA through the DMA, DMA_USEBURSTC needs to be set to 1. This ensures that the data gets picked up even when the receive buffer is half-full.

### 17.3.14 Interrupts

The interrupts generated by the  $I^2C$  module are combined into one interrupt vector,  $I2C_INT$ . If  $I^2C$  interrupts are enabled, an interrupt will be made if one or more of the interrupt flags in  $I2Cn_IEN$  are set.

#### 17.3.15 Wake-up

The I²C receive section can be active all the way down to energy mode EM3 Stop, and can wake up the CPU on address interrupt. All address match modes are supported.

## 17.4 Register Map

The offset register address is relative to the registers base address.

Offset	Name	Туре	Description
0x000	I2Cn_CTRL	RW	Control Register
0x004	I2Cn_CMD	W1	Command Register
0x008	I2Cn_STATE	R	State Register
0x00C	I2Cn_STATUS	R	Status Register

31:19	Reserved	To ensure co	mpatibility	with future devices, always write bits to 0. More information in 1.2 Conven-
18:16	CLTO	0x0	RW	Clock Low Timeout

Use to generate a timeout when CLK has been low for the given amount of time. Wraps around and continues counting when the timeout is reached. The timeout value can be calculated by

timeout = 
$$PCC/(f_{SCL} x (N_{low} + N_{high}))$$

	Value	Mode	Description
	0	OFF	Timeout disabled
	1	40PCC	Timeout after 40 prescaled clock cycles. In standard mode at 100 kHz, this results in a 50us timeout.
	2	80PCC	Timeout after 80 prescaled clock cycles. In standard mode at 100 kHz, this results in a 100us timeout.
	3	160PCC	Timeout after 160 prescaled clock cycles. In standard mode at 100 kHz, this results in a 200us timeout.
	4	320PCC	Timeout after 320 prescaled clock cycles. In standard mode at 100 kHz, this results in a 400us timeout.
	5	1024PCC	Timeout after 1024 prescaled clock cycles. In standard mode at 100 kHz, this results in a 1280us timeout.
15	GIBITO	0 RW	Go Idle on Bus Idle Timeout
	When set, the bus	s automatically goes idle or	a bus idle timeout, allowing new transfers to be initiated.
	Value		Description
	0		A bus idle timeout has no effect on the bus state.
	1		A bus idle timeout tells the $I^2C$ module that the bus is idle, allowing new transfers to be initiated.
14	Reserved	To ensure compatibil tions	lity with future devices, always write bits to 0. More information in 1.2 Conven-

Bit	Name	Reset	Access	Description
13:12	BITO	0x0	RW	Bus Idle Timeout

Use to generate a timeout when SCL has been high for a given amount time between a START and STOP condition. When in a bus transaction, i.e. the BUSY flag is set, a timer is started whenever SCL goes high. When the timer reaches the value defined by BITO, it sets the BITO interrupt flag. The BITO interrupt flag will then be set periodically as long as SCL remains high. The bus idle timeout is active as long as BUSY is set. It is thus stopped automatically on a timeout if GIBITO is set. It is also stopped a STOP condition is detected and when the ABORT command is issued. The timeout is activated whenever the bus goes BUSY, i.e. a START condition is detected. The timeout value can be calculated by

timeout = 
$$PCC/(f_{SCL} x (N_{low} + N_{high}))$$

	Value	Mode	Description
	0	OFF	Timeout disabled
	1	40PCC	Timeout after 40 prescaled clock cycles. In standard mode at 100 kHz, this results in a 50us timeout.
	2	80PCC	Timeout after 80 prescaled clock cycles. In standard mode at 100 kHz, this results in a 100us timeout.
	3	160PCC	Timeout after 160 prescaled clock cycles. In standard mode at 100 kHz, this results in a 200us timeout.
11:10	Reserved	To ensure compati	bility with future devices, always write bits to 0. More information in 1.2 Conven-
9:8	CLHR	0x0 RW	Clock Low High Ratio
	Determines the i	ratio between the low and	high parts of the clock signal generated on SCL as master.
	Value	Mode	Description
	0	STANDARD	The ratio between low period and high period counters ( $N_{low}$ : $N_{high}$ ) is 4:4
	1	ASYMMETRIC	The ratio between low period and high period counters ( $N_{low}$ : $N_{high}$ ) is 6:3
	2	FAST	The ratio between low period and high period counters ( $N_{low}$ : $N_{high}$ ) is 11:6
7	TXBIL	0 RW	TX Buffer Interrupt Level
	Determines the i	interrupt and status level o	f the transmit buffer.
	Value	Mode	Description
	0	EMPTY	TXBL status and the TXBL interrupt flag are set when the transmit buf- fer becomes empty. TXBL is cleared when the buffer becomes non- empty.
	1	HALFFULL	TXBL status and the TXBL interrupt flag are set when the transmit buf- fer goes from full to half-full or empty. TXBL is cleared when the buffer becomes full.
6	GCAMEN	0 RW	General Call Address Match Enable
	Set to enable ad	dress match on general ca	all in addition to the programmed slave address.
	Value		Description
	0		General call address will be NACK'ed if it is not included by the slave address and address mask.

Bit	Namo	Posot	Accese	Description
БП	Name 1	Reset	Access	When a general call address is received, a software response is re-
				quired.
5	ARBDIS	0	RW	Arbitration Disable
	A master or slav	e will not release t	he bus upon l	losing arbitration.
	Value			Description
	0			When a device loses arbitration, the ARB interrupt flag is set and the bus is released.
	1			When a device loses arbitration, the ARB interrupt flag is set, but communication proceeds.
4	AUTOSN	0	RW	Automatic STOP on NACK
	Write to 1 to make	ke a master transn	nitter send a S	STOP when a NACK is received from a slave.
	Value			Description
	0			Stop is not automatically sent if a NACK is received from a slave.
	1			The master automatically sends a STOP if a NACK is received from a slave.
3	AUTOSE	0	RW	Automatic STOP When Empty
	Write to 1 to make	ke a master transn	nitter send a S	STOP when no more data is available for transmission.
	Value			Description
	0			A stop must be sent manually when no more data is to be transmitted.
	1			The master automatically sends a STOP when no more data is available for transmission.
2	AUTOACK	0	RW	Automatic Acknowledge
	Set to enable au	tomatic acknowled	dges.	
	Value			Description
	0			Software must give one ACK command for each ACK transmitted on the I ² C bus.
	1			Addresses that are not automatically NACK'ed, and all data is automatically acknowledged.
1	SLAVE	0	RW	Addressable as Slave
	Set this bit to allo	ow the device to b	e selected as	an I ² C slave.
	Value			Description
	0			All addresses will be responded to with a NACK
	1			Addresses matching the programmed slave address or the general call address (if enabled) require a response from software. Other addresses are automatically responded to with a NACK.
0	EN	0	RW	I ² C Enable
	Use this bit to en	nable or disable the	e I ² C module.	

Bit	Name	Reset	Access	Description						
	Value			Description						
	0			The I ² C module is disabled. And its internal state is cleared						
	1			The I ² C module is enabled.

				SST SST SST SST SST BUS BUS BUS BUS BUS ACK ACK ACK ACK ADD ADD ADD ADD ADD ADD ADD ADD ADD AD
Bit	Name	Reset	Access	Description
31:19	Reserved	To ensure co	ompatibility	with future devices, always write bits to 0. More information in 1.2 Conven-
18	CLERR	0	R	Clock Low Error Interrupt Flag
	Set when the clock	is pulled low before	ore a STAR	T or a STOP condition could be transmitted.
17	RXFULL	0	R	Receive Buffer Full Interrupt Flag
	Set when the receiv	e buffer become	s full.	
16	SSTOP	0	R	Slave STOP Condition Interrupt Flag
	Set when a STOP of	ondition has bee	en received.	Will be set regardless of the slave being involved in the transaction or not.
15	CLTO	0	R	Clock Low Timeout Interrupt Flag
	Set on each clock lo	w timeout. The	timeout valu	e can be set in CLTO bit field in the I2Cn_CTRL register.
14	BITO	0	R	Bus Idle Timeout Interrupt Flag
	Set on each bus idle	e timeout. The tir	meout value	can be set in the BITO bit field in the I2Cn_CTRL register.
13	RXUF	0	R	Receive Buffer Underflow Interrupt Flag
				rough the I2Cn_RXDATA register while the receive buffer is empty. It is CDOUBLE while the buffer is not full.
12	TXOF	0	R	Transmit Buffer Overflow Interrupt Flag
	Set when data is wr	itten to the trans	mit buffer w	hile the transmit buffer is full.
11	BUSHOLD	0	R	Bus Held Interrupt Flag
	Set when the bus be	ecomes held by	the I ² C mod	ule.
10	BUSERR	0	R	Bus Error Interrupt Flag
	Set when a bus erro	or is detected. Th	ne bus error	is resolved automatically, but the current transfer is aborted.
9	ARBLOST	0	R	Arbitration Lost Interrupt Flag
	Set when arbitration	is lost.		
8	MSTOP	0	R	Master STOP Condition Interrupt Flag
	Set when a STOP condition, then the N			ully transmitted. If arbitration is lost during the transmission of the STOP set.
7	NACK	0	R	Not Acknowledge Received Interrupt Flag
	Set when a NACK h	as been receive	d.	
6	ACK	0	R	Acknowledge Received Interrupt Flag
	Set when an ACK h	as been received	d	

Bit	Name	Reset	Access	Description
5	RXDATAV	0	R	Receive Data Valid Interrupt Flag
	Set when data is	available in the re	eceive buffer.	Cleared automatically when the receive buffer is read.
4	TXBL	1	R	Transmit Buffer Level Interrupt Flag
	Set when the train	nsmit buffer becor	mes empty. C	leared automatically when new data is written to the transmit buffer.
3	TXC	0	R	Transfer Completed Interrupt Flag
	Set when the train	nsmit shift registe	r becomes em	npty and there is no more data in the transmit buffer.
2	ADDR	0	R	Address Interrupt Flag
	Set when incomi	ng address is acc	epted, i.e. ow	n address or general call address is received.
1	RSTART	0	R	Repeated START Condition Interrupt Flag
	Set when a repea	ated start conditio	n is detected.	
0	START	0	R	START Condition Interrupt Flag
	Set when a start	condition is succe	essfully transn	nitted.

# 18. USART - Universal Synchronous Asynchronous Receiver/Transmitter

#### **Quick Facts**

#### What?

The USART handles high-speed UART, SPI-bus, SmartCards, and IrDA communication.

# Why?

Serial communication is frequently used in embedded systems and the USART allows efficient communication with a wide range of external devices.

#### How?

The USART has a wide selection of operating modes, frame formats and baud rates. The multi-processor mode allows the USART to remain idle when not addressed. Triple buffering and DMA support makes high data rates possible with minimal CPU intervention and it is possible to transmit and receive large frames while the MCU remains in EM1 Sleep.

# 18.1 Introduction

The Universal Synchronous Asynchronous serial Receiver and Transmitter (USART) is a very flexible serial I/O module. It supports full duplex asynchronous UART communication as well as RS-485, SPI, MicroWire and 3-wire. It can also interface with ISO7816 Smart-Cards, and IrDA devices.

#### 18.2 Features

- · Asynchronous and synchronous (SPI) communication
- · Full duplex and half duplex
- Separate TX/RX enable
- · Separate receive / transmit multiple entry buffers, with additional separate shift registers
- Programmable baud rate, generated as an fractional division from the peripheral clock (HFPERCLK_{USARTn})
- · Max bit-rate
  - SPI master mode, peripheral clock rate/2
  - SPI slave mode, peripheral clock rate/8
  - UART mode, peripheral clock rate/16, 8, 6, or 4
- · Asynchronous mode supports
  - · Majority vote baud-reception
  - · False start-bit detection
  - · Break generation/detection
  - · Multi-processor mode
- · Synchronous mode supports
  - · All 4 SPI clock polarity/phase configurations
  - · Master and slave mode
- · Data can be transmitted LSB first or MSB first
- Configurable number of data bits, 4-16 (plus the parity bit, if enabled)
  - · HW parity bit generation and check
- Configurable number of stop bits in asynchronous mode: 0.5, 1, 1.5, 2
- · HW collision detection
- · Multi-processor mode
- IrDA modulator
- · SmartCard (ISO7816) mode
- · I2S mode
- Separate interrupt vectors for receive and transmit interrupts
- · Loopback mode
  - · Half duplex communication
  - · Communication debugging
- · PRS RX input
- · 8 bit Timer
- · Hardware Flow Control
- · Automatic Baud Rate Detection

# 18.3 Functional Description

An overview of the USART module is shown in Figure 18.1 USART Overview on page 551.

This section describes all possible USART features. Refer to the device data sheet to see what features a specific USART instance supports.

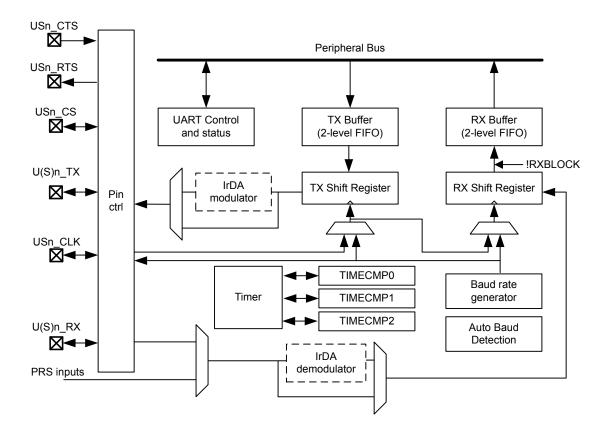

Figure 18.1. USART Overview

# 18.3.1 Modes of Operation

The USART operates in either asynchronous or synchronous mode.

In synchronous mode, a separate clock signal is transmitted with the data. This clock signal is generated by the bus master, and both the master and slave sample and transmit data according to this clock. Both master and slave modes are supported by the USART. The synchronous communication mode is compatible with the Serial Peripheral Interface Bus (SPI) standard.

In asynchronous mode, no separate clock signal is transmitted with the data on the bus. The USART receiver thus has to determine where to sample the data on the bus from the actual data. To make this possible, additional synchronization bits are added to the data when operating in asynchronous mode, resulting in a slight overhead.

Asynchronous or synchronous mode can be selected by configuring SYNC in USARTn_CTRL. The options are listed with supported protocols in Table 18.1 USART Asynchronous Vs. Synchronous Mode on page 552. Full duplex and half duplex communication is supported in both asynchronous and synchronous mode.

Table 18.1. USART Asynchronous Vs. Synchronous Mode

SYNC	Communication Mode	Supported Protocols
0	Asynchronous	RS-232, RS-485 (w/external driver), IrDA, ISO 7816
1	Synchronous	SPI, MicroWire, 3-wire

Table 18.2 USART Pin Usage on page 552 explains the functionality of the different USART pins when the USART operates in different modes. Pin functionality enclosed in square brackets is optional, and depends on additional configuration parameters. LOOPBK and MASTER are discussed in 18.3.2.14 Local Loopback and 18.3.3.3 Master Mode respectively.

Table 18.2. USART Pin Usage

SYNC	LOOPBK	MASTER	Pin functionality				
			U(S)n_TX (MOSI)	U(S)n_RX (MISO)	USn_CLK	USn_CS	
0	0	x	Data out	Data in	-	[Driver enable]	
0	1	х	Data out/in	-	-	[Driver enable]	
1	0	0	Data in	Data out	Clock in	Slave select	
1	0	1	Data out	Data in	Clock out	[Auto slave select]	
1	1	0	Data out/in	-	Clock in	Slave select	
1	1	1	Data out/in	-	Clock out	[Auto slave select]	

# 18.3.2 Asynchronous Operation

The USART operates in asynchronous mode when SYNC in USARTn_CTRL is cleared to 0.

#### 18.3.2.1 Frame Format

The frame format used in asynchronous mode consists of a set of data bits in addition to bits for synchronization and optionally a parity bit for error checking. A frame starts with one start-bit (S), where the line is driven low for one bit-period. This signals the start of a frame, and is used for synchronization. Following the start bit are 4 to 16 data bits and an optional parity bit. Finally, a number of stop-bits, where the line is driven high, end the frame. An example frame is shown in Figure 18.2 USART Asynchronous Frame Format on page 553.

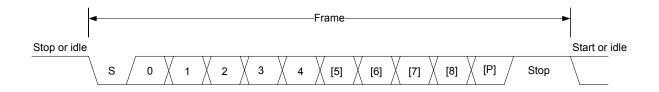

Figure 18.2. USART Asynchronous Frame Format

The number of data bits in a frame is set by DATABITS in USARTn_FRAME, see Table 18.3 USART Data Bits on page 553, and the number of stop-bits is set by STOPBITS in USARTn_FRAME, see Table 18.4 USART Stop Bits on page 553. Whether or not a parity bit should be included, and whether it should be even or odd is defined by PARITY, also in USARTn_FRAME. For communication to be possible, all parties of an asynchronous transfer must agree on the frame format being used.

Table 18.3. USART Data Bits

DATA BITS [3:0]	Number of Data Bits
0001	4
0010	5
0011	6
0100	7
0101	8 (Default)
0110	9
0111	10
1000	11
1001	12
1010	13
1011	14
1100	15
1101	16

Table 18.4. USART Stop Bits

STOP BITS [1:0]	Number of Stop Bits
00	0.5
01	1 (Default)
10	1.5
11	2

The order in which the data bits are transmitted and received is defined by MSBF in USARTn_CTRL. When MSBF is cleared, data in a frame is sent and received with the least significant bit first. When it is set, the most significant bit comes first.

The frame format used by the transmitter can be inverted by setting TXINV in USARTn_CTRL, and the format expected by the receiver can be inverted by setting RXINV in USARTn_CTRL. These bits affect the entire frame, not only the data bits. An inverted frame has a low idle state, a high start-bit, inverted data and parity bits, and low stop-bits.

# 18.3.2.2 Parity Bit Calculation and Handling

When parity bits are enabled, hardware automatically calculates and inserts any parity bits into outgoing frames, and verifies the received parity bits in incoming frames. This is true for both asynchronous and synchronous modes, even though it is mostly used in asynchronous communication. The possible parity modes are defined in Table 18.5 USART Parity Bits on page 554. When even parity is chosen, a parity bit is inserted to make the number of high bits (data + parity) even. If odd parity is chosen, the parity bit makes the total number of high bits odd.

Table 18.5. USART Parity Bits

PARITY BITS [1:0]	Description	
00	No parity bit (Default)	
01	Reserved	
10	Even parity	
11	Odd parity	

#### 18.3.2.3 Clock Generation

The USART clock defines the transmission and reception data rate. When operating in asynchronous mode, the baud rate (bit-rate) is given by Figure 18.3 USART Baud Rate on page 555.

br = f_{HFPERCLK}/(oversample x (1 + USARTn_CLKDIV/256))

### Figure 18.3. USART Baud Rate

where f_{HFPERCLK} is the peripheral clock (HFPERCLK_{USARTn}) frequency and oversample is the oversampling rate as defined by OVS in USARTn_CTRL, see Table 18.6 USART Oversampling on page 555.

Table 18.6. USART Oversampling

OVS [1:0]	Oversample
00	16
01	8
10	6
11	4

The USART has a fractional clock divider to allow the USART clock to be controlled more accurately than what is possible with a standard integral divider.

The clock divider used in the USART is a 20-bit value, with a 15-bit integral part and an 5-bit fractional part. The fractional part is configured in the lower 5 bits of DIV in USART CLKDIV.

Fractional clock division is implemented by distributing the selected fraction over thirty two baud periods. The fractional part of the divider tells how many of these periods should be extended by one peripheral clock cycle.

Given a desired baud rate brdesired, the clock divider USARTn_CLKDIV can be calculated by using Figure 18.4 USART Desired Baud Rate on page 555:

USARTn_CLKDIV = 256 x (f_{HFPERCLK}/(oversample x brdesired) - 1)

# Figure 18.4. USART Desired Baud Rate

Table 18.7 USART Baud Rates @ 4MHz Peripheral Clock With 20 Bit CLKDIV on page 555 shows a set of desired baud rates and how accurately the USART is able to generate these baud rates when running at a 4 MHz peripheral clock, using 16x or 8x oversampling.

Table 18.7. USART Baud Rates @ 4MHz Peripheral Clock With 20 Bit CLKDIV

#### 18.3.2.4 Auto Baud Detection

Setting AUTOBAUDEN in USARTn_CLKDIV uses the first frame received to automatically set the baud rate provided that it contains 0x55 (IrDA uses 0x00). AUTOBAUDEN can be used in a simple LIN configuration to auto detect the SYNC byte. The receiver will measure the number of local clock cycles between the beginning of the START bit and the beginning of the 8th data bit. The DIV field in USARTn_CLKDIV will be overwritten with the new value. The OVS in USARTn_CTRL and the +1 count of the Baud Rate equation are already factored into the result that gets written into the DIV field. To restart autobaud detection, clear AUTOBAUDEN and set it high again. Since the auto baud detection is done over 8 baud times, only the upper 3 bits of the fractional part of the clock divider are populated.

#### 18.3.2.5 Data Transmission

Asynchronous data transmission is initiated by writing data to the transmit buffer using one of the methods described in 18.3.2.6 Transmit Buffer Operation. When the transmission shift register is empty and ready for new data, a frame from the transmit buffer is loaded into the shift register, and if the transmitter is enabled, transmission begins. When the frame has been transmitted, a new frame is loaded into the shift register if available, and transmission continues. If the transmit buffer is empty, the transmitter goes to an idle state, waiting for a new frame to become available.

Transmission is enabled through the command register USARTn_CMD by setting TXEN, and disabled by setting TXDIS in the same command register. When the transmitter is disabled using TXDIS, any ongoing transmission is aborted, and any frame currently being transmitted is discarded. When disabled, the TX output goes to an idle state, which by default is a high value. Whether or not the transmitter is enabled at a given time can be read from TXENS in USARTn_STATUS.

When the USART transmitter is enabled and there is no data in the transmit shift register or transmit buffer, the TXC flag in USARTn_STATUS and the TXC interrupt flag in USARTn_IF are set, signaling that the transmission is complete. The TXC status flag is cleared when a new frame becomes available for transmission, but the TXC interrupt flag must be cleared by software.

#### 18.3.2.6 Transmit Buffer Operation

The transmit-buffer is a multiple entry FIFO buffer. A frame can be loaded into the buffer by writing to USARTn_TXDATA, USARTn_TXDATAX, USARTn_TXDOUBLE or USARTn_TXDOUBLEX. Using USARTn_TXDATA allows 8 bits to be written to the buffer, while using USARTn_TXDOUBLE will write 2 frames of 8 bits to the buffer. If 9-bit frames are used, the 9th bit of the frames will in these cases be set to the value of BIT8DV in USARTn_CTRL.

To set the 9th bit directly and/or use transmission control, USARTn_TXDATAX and USARTn_TXDOUBLEX must be used. USARTn_TXDATAX allows 9 data bits to be written, as well as a set of control bits regarding the transmission of the written frame. Every frame in the buffer is stored with 9 data bits and additional transmission control bits. USARTn_TXDOUBLEX allows two frames, complete with control bits to be written at once. When data is written to the transmit buffer using USARTn_TXDATAX and USARTn_TXDOUBLEX, the 9th bit(s) written to these registers override the value in BIT8DV in USARTn_CTRL, and alone define the 9th bits that are transmitted if 9-bit frames are used. Figure 18.5 USART Transmit Buffer Operation on page 557 shows the basics of the transmit buffer when DATABITS in USARTn_FRAME is configured to less than 10 bits.

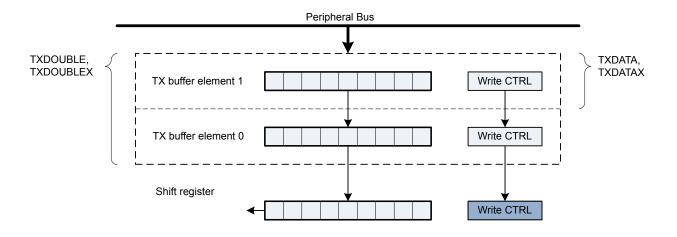

Figure 18.5. USART Transmit Buffer Operation

When writing more frames to the transmit buffer than there is free space for, the TXOF interrupt flag in USARTn_IF will be set, indicating the overflow. The data already in the transmit buffer is preserved in this case, and no data is written.

In addition to the interrupt flag TXC in USARTn_IF and status flag TXC in USARTn_STATUS which are set when the transmission is complete, TXBL in USARTn_STATUS and the TXBL interrupt flag in USARTn_IF are used to indicate the level of the transmit buffer. TXBIL in USARTn_CTRL controls the level at which these bits are set. If TXBIL is cleared, they are set whenever the transmit buffer becomes empty, and if TXBIL is set, they are set whenever the transmit buffer goes from full to half-full or empty. Both the TXBL status flag and the TXBL interrupt flag are cleared automatically when their condition becomes false.

There is a TXIDLE status bit in USARTn_STATUS to provide an indication of when the transmitter is idle. The combined count of TX buffer element 0, TX buffer element 1, and TX shift register is called TXBUFCNT in USARTn_STATUS. For large frames, the count is only of TX buffer entry 0 and the TX shifter register.

The transmit buffer, including the transmit shift register can be cleared by setting CLEARTX in USARTn_CMD. This will prevent the USART from transmitting the data in the buffer and shift register, and will make them available for new data. Any frame currently being transmitted will not be aborted. Transmission of this frame will be completed.

#### 18.3.2.7 Frame Transmission Control

The transmission control bits, which can be written using USARTn_TXDATAX and USARTn_TXDOUBLEX, affect the transmission of the written frame. The following options are available:

- Generate break: By setting TXBREAK, the output will be held low during the stop-bit period to generate a framing error. A receiver that supports break detection detects this state, allowing it to be used e.g. for framing of larger data packets. The line is driven high before the next frame is transmitted so the next start condition can be identified correctly by the recipient. Continuous breaks lasting longer than a USART frame are thus not supported by the USART. GPIO can be used for this.
- Disable transmitter after transmission: If TXDISAT is set, the transmitter is disabled after the frame has been fully transmitted.
- Enable receiver after transmission: If RXENAT is set, the receiver is enabled after the frame has been fully transmitted. It is enabled in time to detect a start-bit directly after the last stop-bit has been transmitted.
- Unblock receiver after transmission: If UBRXAT is set, the receiver is unblocked and RXBLOCK is cleared after the frame has been fully transmitted.
- Tristate transmitter after transmission: If TXTRIAT is set, TXTRI is set after the frame has been fully transmitted, tristating the transmitter output. Tristating of the output can also be performed automatically by setting AUTOTRI. If AUTOTRI is set TXTRI is always read as 0.

**Note:** When in SmartCard mode with repeat enabled, none of the actions, except generate break, will be performed until the frame is transmitted without failure. Generation of a break in SmartCard mode with repeat enabled will cause the USART to detect a NACK on every frame.

# 18.3.2.8 Data Reception

Data reception is enabled by setting RXEN in USARTn_CMD. When the receiver is enabled, it actively samples the input looking for a transition from high to low indicating the start baud of a new frame. When a start baud is found, reception of the new frame begins if the receive shift register is empty and ready for new data. When the frame has been received, it is pushed into the receive buffer, making the shift register ready for another frame of data, and the receiver starts looking for another start baud. If the receive buffer is full, the received frame remains in the shift register until more space in the receive buffer is available. If an incoming frame is detected while both the receive buffer and the receive shift register are full, the data in the shift register is overwritten, and the RXOF interrupt flag in USARTn_IF is set to indicate the buffer overflow.

The receiver can be disabled by setting the command bit RXDIS in USARTn_CMD. Any frame currently being received when the receiver is disabled is discarded. Whether or not the receiver is enabled at a given time can be read out from RXENS in USARTn_STATUS.

#### 18.3.2.9 Receive Buffer Operation

When data becomes available in the receive buffer, the RXDATAV flag in USARTn_STATUS, and the RXDATAV interrupt flag in USARTn_IF are set, and when the buffer becomes full, RXFULL in USARTn_STATUS and the RXFULL interrupt flag in USARTn_IF are set. The status flags RXDATAV and RXFULL are automatically cleared by hardware when their condition is no longer true. This also goes for the RXDATAV interrupt flag, but the RXFULL interrupt flag must be cleared by software. When the RXFULL flag is set, notifying that the buffer is full, space is still available in the receive shift register for one more frame.

Data can be read from the receive buffer in a number of ways. USARTn_RXDATA gives access to the 8 least significant bits of the received frame, and USARTn_RXDOUBLE makes it possible to read the 8 least significant bits of two frames at once, pulling two frames from the buffer. To get access to the 9th, most significant bit, USARTn_RXDATAX must be used. This register also contains status information regarding the frame. USARTn_RXDOUBLEX can be used to get two frames complete with the 9th bits and status bits.

When a frame is read from the receive buffer using USARTn_RXDATA or USARTn_RXDATAX, the frame is pulled out of the buffer, making room for a new frame. USARTn_RXDOUBLE and USARTn_RXDOUBLEX pull two frames out of the buffer. If an attempt is done to read more frames from the buffer than what is available, the RXUF interrupt flag in USARTn_IF is set to signal the underflow, and the data read from the buffer is undefined.

Frames can be read from the receive buffer without removing the data by using USARTn_RXDATAXP and USARTn_RXDOUBLEXP. USARTn_RXDATAXP gives access the first frame in the buffer with status bits, while USARTn_RXDOUBLEXP gives access to both frames with status bits. The data read from these registers when the receive buffer is empty is undefined. If the receive buffer contains one valid frame, the first frame in USARTn_RXDOUBLEXP will be valid. No underflow interrupt is generated by a read using these registers, i.e. RXUF in USARTn_IF is never set as a result of reading from USARTn_RXDATAXP or USARTn_RXDOUBLEXP.

The basic operation of the receive buffer when DATABITS in USARTn_FRAME is configured to less than 10 bits is shown in Figure 18.6 USART Receive Buffer Operation on page 559.

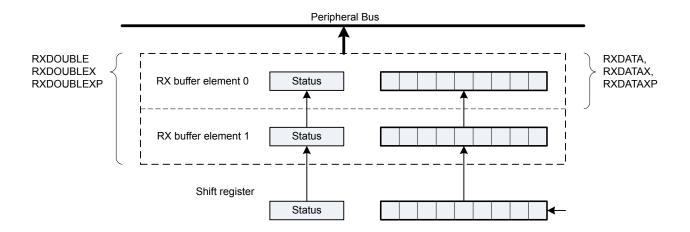

Figure 18.6. USART Receive Buffer Operation

The receive buffer, including the receive shift register can be cleared by setting CLEARRX in USARTn_CMD. Any frame currently being received will not be discarded.

## 18.3.2.10 Blocking Incoming Data

When using hardware frame recognition, as detailed in 18.3.2.20 Multi-Processor Mode and 18.3.2.21 Collision Detection, it is necessary to be able to let the receiver sample incoming frames without passing the frames to software by loading them into the receive buffer. This is accomplished by blocking incoming data.

Incoming data is blocked as long as RXBLOCK in USARTn_STATUS is set. When blocked, frames received by the receiver will not be loaded into the receive buffer, and software is not notified by the RXDATAV flag in USARTn_STATUS or the RXDATAV interrupt flag in USARTn_IF at their arrival. For data to be loaded into the receive buffer, RXBLOCK must be cleared in the instant a frame is fully received by the receiver. RXBLOCK is set by setting RXBLOCKEN in USARTn_CMD and disabled by setting RXBLOCKDIS also in USARTn_CMD. There is one exception where data is loaded into the receive buffer even when RXBLOCK is set. This is when an address frame is received when operating in multi-processor mode. See 18.3.2.20 Multi-Processor Mode for more information.

Frames received containing framing or parity errors will not result in the FERR and PERR interrupt flags in USARTn_IF being set while RXBLOCK in USARTn_STATUS is set. Hardware recognition is not applied to these erroneous frames, and they are silently discarded.

#### Note:

- If a frame is received while RXBLOCK in USARTn_STATUS is cleared, but stays in the receive shift register because the receive buffer is full, the received frame will be loaded into the receive buffer when space becomes available even if RXBLOCK is set at that time.
- The overflow interrupt flag RXOF in USARTn_IF will be set if a frame in the receive shift register, waiting to be loaded into the receive buffer is overwritten by an incoming frame even though RXBLOCK in USARTn_STATUS is set.

# 18.3.2.11 Clock Recovery and Filtering

The receiver samples the incoming signal at a rate 16, 8, 6 or 4 times higher than the given baud rate, depending on the oversampling mode given by OVS in USARTn CTRL. Lower oversampling rates make higher baud rates possible, but give less room for errors.

When a high-to-low transition is registered on the input while the receiver is idle, this is recognized as a start-bit, and the baud rate generator is synchronized with the incoming frame.

For oversampling modes 16, 8 and 6, every bit in the incoming frame is sampled three times to gain a level of noise immunity. These samples are aimed at the middle of the bit-periods, as visualized in Figure 18.7 USART Sampling of Start and Data Bits on page 561. With OVS=0 in USARTn_CTRL, the start and data bits are thus sampled at locations 8, 9 and 10 in the figure, locations 4, 5 and 6 for OVS=1 and locations 3, 4, and 5 for OVS=2. The value of a sampled bit is determined by majority vote. If two or more of the three bit-samples are high, the resulting bit value is high. If the majority is low, the resulting bit value is low.

Majority vote is used for all oversampling modes except 4x oversampling. In this mode, a single sample is taken at position 3 as shown in Figure 18.7 USART Sampling of Start and Data Bits on page 561.

Majority vote can be disabled by setting MVDIS in USARTn CTRL.

If the value of the start bit is found to be high, the reception of the frame is aborted, filtering out false start bits possibly generated by noise on the input.

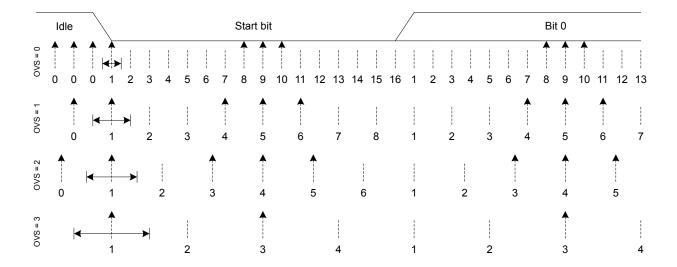

Figure 18.7. USART Sampling of Start and Data Bits

If the baud rate of the transmitter and receiver differ, the location each bit is sampled will be shifted towards the previous or next bit in the frame. This is acceptable for small errors in the baud rate, but for larger errors, it will result in transmission errors.

When the number of stop bits is 1 or more, stop bits are sampled like the start and data bits as seen in Figure 18.8 USART Sampling of Stop Bits when Number of Stop Bits are 1 or More on page 562. When a stop bit has been detected by sampling at positions 8, 9 and 10 for normal mode, or 4, 5 and 6 for smart mode, the USART is ready for a new start bit. As seen in Figure 18.8 USART Sampling of Stop Bits when Number of Stop Bits are 1 or More on page 562, a stop-bit of length 1 normally ends at c, but the next frame will be received correctly as long as the start-bit comes after position a for OVS=0 and OVS=3, and b for OVS=1 and OVS=2.

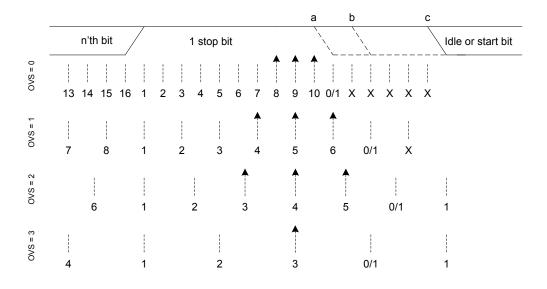

Figure 18.8. USART Sampling of Stop Bits when Number of Stop Bits are 1 or More

When working with stop bit lengths of half a baud period, the above sampling scheme no longer suffices. In this case, the stop-bit is not sampled, and no framing error is generated in the receiver if the stop-bit is not generated. The line must still be driven high before the next start bit however for the USART to successfully identify the start bit.

#### 18.3.2.12 Parity Error

When parity bits are enabled, a parity check is automatically performed on incoming frames. When a parity error is detected in an incoming frame, the data parity error bit PERR in the frame is set, as well as the interrupt flag PERR in USARTn_IF. Frames with parity errors are loaded into the receive buffer like regular frames.

PERR can be accessed by reading the frame from the receive buffer using the USARTn_RXDATAX, USARTn_RXDATAXP, USARTn RXDOUBLEX or USARTn RXDOUBLEXP registers.

If ERRSTX in USARTn_CTRL is set, the transmitter is disabled on received parity and framing errors. If ERRSRX in USARTn_CTRL is set, the receiver is disabled on parity and framing errors.

# 18.3.2.13 Framing Error and Break Detection

A framing error is the result of an asynchronous frame where the stop bit was sampled to a value of 0. This can be the result of noise and baud rate errors, but can also be the result of a break generated by the transmitter on purpose.

When a framing error is detected in an incoming frame, the framing error bit FERR in the frame is set. The interrupt flag FERR in USARTn IF is also set. Frames with framing errors are loaded into the receive buffer like regular frames.

FERR can be accessed by reading the frame from the receive buffer using the USARTn_RXDATAX, USARTn_RXDATAXP, USARTn_RXDOUBLEX or USARTn_RXDOUBLEXP registers.

If ERRSTX in USARTn_CTRL is set, the transmitter is disabled on parity and framing errors. If ERRSRX in USARTn_CTRL is set, the receiver is disabled on parity and framing errors.

#### 18.3.2.14 Local Loopback

The USART receiver samples U(S)n_RX by default, and the transmitter drives U(S)n_TX by default. This is not the only option however. When LOOPBK in USARTn_CTRL is set, the receiver is connected to the U(S)n_TX pin as shown in Figure 18.9 USART Local Loopback on page 563. This is useful for debugging, as the USART can receive the data it transmits, but it is also used to allow the USART to read and write to the same pin, which is required for some half duplex communication modes. In this mode, the U(S)n_TX pin must be enabled as an output in the GPIO.

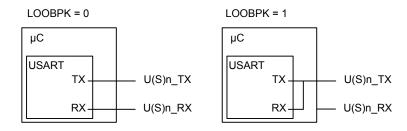

Figure 18.9. USART Local Loopback

#### 18.3.2.15 Asynchronous Half Duplex Communication

When doing full duplex communication, two data links are provided, making it possible for data to be sent and received at the same time. In half duplex mode, data is only sent in one direction at a time. There are several possible half duplex setups, as described in the following sections.

#### 18.3.2.16 Single Data-link

In this setup, the USART both receives and transmits data on the same pin. This is enabled by setting LOOPBK in USARTn_CTRL, which connects the receiver to the transmitter output. Because they are both connected to the same line, it is important that the USART transmitter does not drive the line when receiving data, as this would corrupt the data on the line.

When communicating over a single data-link, the transmitter must thus be tristated whenever not transmitting data. This is done by setting the command bit TXTRIEN in USARTn_CMD, which tristates the transmitter. Before transmitting data, the command bit TXTRI-DIS, also in USARTn_CMD, must be set to enable transmitter output again. Whether or not the output is tristated at a given time can be read from TXTRI in USARTn_STATUS. If TXTRI is set when transmitting data, the data is shifted out of the shift register, but is not put out on U(S)n_TX.

When operating a half duplex data bus, it is common to have a bus master, which first transmits a request to one of the bus slaves, then receives a reply. In this case, the frame transmission control bits, which can be set by writing to USARTn_TXDATAX, can be used to make the USART automatically disable transmission, tristate the transmitter and enable reception when the request has been transmitted, making it ready to receive a response from the slave.

The timer, 18.3.10 Timer, can also be used to add delay between the RX and TX frames so that the interrupt service routine has time to process data that was just received before transmitting more data. Also hardware flow control is another method to insert time for processing the frame. RTS and CTS can be used to halt either the link partner's transmitter or the local transmitter. See the section on hardware flow control, 18.3.4 Hardware Flow Control, for more details.

Tristating the transmitter can also be performed automatically by the USART by using AUTOTRI in USARTn_CTRL. When AUTOTRI is set, the USART automatically tristates U(S)n_TX whenever the transmitter is idle, and enables transmitter output when the transmitter goes active. If AUTOTRI is set TXTRI is always read as 0.

**Note:** Another way to tristate the transmitter is to enable wired-and or wired-or mode in GPIO. For wired-and mode, outputting a 1 will be the same as tristating the output, and for wired-or mode, outputting a 0 will be the same as tristating the output. This can only be done on buses with a pull-up or pull-down resistor respectively.

## 18.3.2.17 Single Data-link With External Driver

Some communication schemes, such as RS-485 rely on an external driver. Here, the driver has an extra input which enables it, and instead of tristating the transmitter when receiving data, the external driver must be disabled.

This can be done manually by assigning a GPIO to turn the driver on or off, or it can be handled automatically by the USART. If AUTOCS in USARTn_CTRL is set, the USn_CS output is automatically activated a configurable number of baud periods before the transmitter starts transmitting data, and deactivated a configurable number of baud periods after the last bit has been transmitted and there is no more data in the transmit buffer to transmit. The number of baud periods are controlled by CSSETUP and CSHOLD in USARTn_TIMING. This feature can be used to turn the external driver on when transmitting data, and turn it off when the data has been transmitted.

The timer, 18.3.10 Timer, can also be used to configure CSSETUP and CSHOLD values between 1 to 256 baud-times by using TCMPVAL0, TCMPVAL1, or TCMPVAL2 for the TX sequencer.

USn CS is immediately deasserted when the transmitter becomes disabled.

Figure 18.10 USART Half Duplex Communication with External Driver on page 564 shows an example configuration where USn_CS is used to automatically enable and disable an external driver.

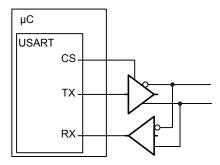

Figure 18.10. USART Half Duplex Communication with External Driver

The USn_CS output is active low by default, but its polarity can be changed with CSINV in USARTn_CTRL. AUTOCS works regardless of which mode the USART is in, so this functionality can also be used for automatic chip/slave select when in synchronous mode (e.g. SPI).

### 18.3.2.18 Two Data-links

Some limited devices only support half duplex communication even though two data links are available. In this case software is responsible for making sure data is not transmitted when incoming data is expected.

TXARXnEN in USARTn_TRIGCTRL may be used to automatically start transmission after the end of the RX frame plus any TXSTDE-LAY and CSSETUP delay in USARTn_TIMING. For enabling the receiver either use RXENAT in USARTn_TXDATAX or RXATXnEN in USARTn_TRIGCTRL.

#### 18.3.2.19 Large Frames

As each frame in the transmit and receive buffers holds a maximum of 9 bits, both the elements in the buffers are combined when working with USART-frames of 10 or more data bits.

To transmit such a frame, at least two elements must be available in the transmit buffer. If only one element is available, the USART will wait for the second element before transmitting the combined frame. Both the elements making up the frame are consumed when transmitting such a frame.

When using large frames, the 9th bits in the buffers are unused. For an 11 bit frame, the 8 least significant bits are thus taken from the first element in the buffer, and the 3 remaining bits are taken from the second element as shown in Figure 18.11 USART Transmission of Large Frames on page 565. The first element in the transmit buffer, i.e. element 0 in Figure 18.11 USART Transmission of Large Frames on page 565 is the first element written to the FIFO, or the least significant byte when writing two bytes at a time using USARTn_TXDOUBLE.

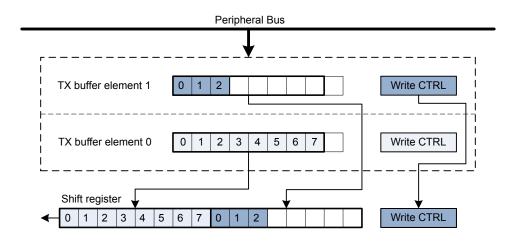

Figure 18.11. USART Transmission of Large Frames

As shown in Figure 18.11 USART Transmission of Large Frames on page 565, frame transmission control bits are taken from the second element in FIFO.

The two buffer elements can be written at the same time using the USARTn_TXDOUBLE or USARTn_TXDOUBLEX register. The TXDATAX0 bitfield then refers to buffer element 0, and TXDATAX1 refers to buffer element 1.

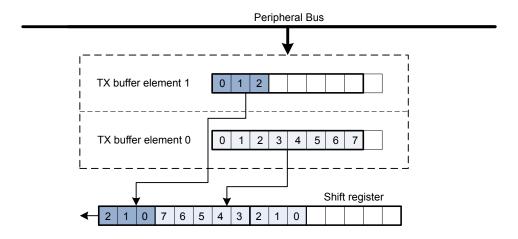

Figure 18.12. USART Transmission of Large Frames, MSBF

Figure 18.12 USART Transmission of Large Frames, MSBF on page 565 illustrates the order of the transmitted bits when an 11 bit frame is transmitted with MSBF set. If MSBF is set and the frame is smaller than 10 bits, only the contents of transmit buffer 0 will be transmitted.

When receiving a large frame, BYTESWAP in USARTn_CTRL determines the order the way the large frame is split into the two buffer elements. If BYTESWAP is cleared, the least significant 8 bits of the received frame are loaded into the first element of the receive buffer, and the remaining bits are loaded into the second element, as shown in Figure 18.13 USART Reception of Large Frames on page 566. The first byte read from the buffer thus contains the 8 least significant bits. Set BYTESWAP to reverse the order.

The status bits are loaded into both elements of the receive buffer. The frame is not moved from the receive shift register before there are two free spaces in the receive buffer.

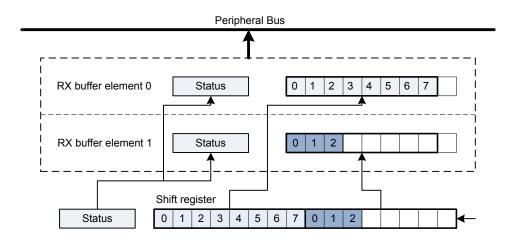

Figure 18.13. USART Reception of Large Frames

The two buffer elements can be read at the same time using the USARTn_RXDOUBLE or USARTn_RXDOUBLEX register. RXDATA0 then refers to buffer element 0 and RXDATA1 refers to buffer element 1.

Large frames can be used in both asynchronous and synchronous modes.

#### 18.3.2.20 Multi-Processor Mode

To simplify communication between multiple processors, the USART supports a special multi-processor mode. In this mode the 9th data bit in each frame is used to indicate whether the content of the remaining 8 bits is data or an address.

When multi-processor mode is enabled, an incoming 9-bit frame with the 9th bit equal to the value of MPAB in USARTn_CTRL is identified as an address frame. When an address frame is detected, the MPAF interrupt flag in USARTn_IF is set, and the address frame is loaded into the receive register. This happens regardless of the value of RXBLOCK in USARTn_STATUS.

Multi-processor mode is enabled by setting MPM in USARTn_CTRL, and the value of the 9th bit in address frames can be set in MPAB. Note that the receiver must be enabled for address frames to be detected. The receiver can be blocked however, preventing data from being loaded into the receive buffer while looking for address frames.

Basic usage of the multi-processor mode is as follows:

- 1. All slaves enable multi-processor mode and, enable and block the receiver. They will now not receive data unless it is an address frame. MPAB in USARTn CTRL is set to identify frames with the 9th bit high as address frames.
- 2. The master sends a frame containing the address of a slave and with the 9th bit set
- 3. All slaves receive the address frame and get an interrupt. They can read the address from the receive buffer. The selected slave unblocks the receiver to start receiving data from the master.
- 4. The master sends data with the 9th bit cleared
- 5. Only the slave with RX enabled receives the data. When transmission is complete, the slave blocks the receiver and waits for a new address frame.

When a slave has received an address frame and wants to receive the following data, it must make sure the receiver is unblocked before the next frame has been completely received in order to prevent data loss.

BIT8DV in USARTn_CTRL can be used to specify the value of the 9th bit without writing to the transmit buffer with USARTn_TXDATAX or USARTn_TXDOUBLEX, giving higher efficiency in multi-processor mode, as the 9th bit is only set when writing address frames, and 8-bit writes to the USART can be used when writing the data frames.

#### 18.3.2.21 Collision Detection

The USART supports a basic form of collision detection. When the receiver is connected to the output of the transmitter, either by using the LOOPBK bit in USARTn_CTRL or through an external connection, this feature can be used to detect whether data transmitted on the bus by the USART did get corrupted by a simultaneous transmission by another device on the bus.

For collision detection to be enabled, CCEN in USARTn_CTRL must be set, and the receiver enabled. The data sampled by the receiver is then continuously compared with the data output by the transmitter. If they differ, the CCF interrupt flag in USARTn_IF is set. The collision check includes all bits of the transmitted frames. The CCF interrupt flag is set once for each bit sampled by the receiver that differs from the bit output by the transmitter. When the transmitter output is disabled, i.e. the transmitter is tristated, collisions are not registered.

#### 18.3.2.22 SmartCard Mode

In SmartCard mode, the USART supports the ISO 7816 I/O line T0 mode. With exception of the stop-bits (guard time), the 7816 data frame is equal to the regular asynchronous frame. In this mode, the receiver pulls the line low for one baud, half a baud into the guard time to indicate a parity error. This NAK can for instance be used by the transmitter to re-transmit the frame. SmartCard mode is a half duplex asynchronous mode, so the transmitter must be tristated whenever not transmitting data.

To enable SmartCard mode, set SCMODE in USARTn_CTRL, set the number of databits in a frame to 8, and configure the number of stopbits to 1.5 by writing to STOPBITS in USARTn_FRAME.

The SmartCard mode relies on half duplex communication on a single line, so for it to work, both the receiver and transmitter must work on the same line. This can be achieved by setting LOOPBK in USARTn_CTRL or through an external connection. The TX output should be configured as open-drain in the GPIO module.

When no parity error is identified by the receiver, the data frame is as shown in Figure 18.14 USART ISO 7816 Data Frame Without Error on page 568. The frame consists of 8 data bits, a parity bit, and 2 stop bits. The transmitter does not drive the output line during the guard time.

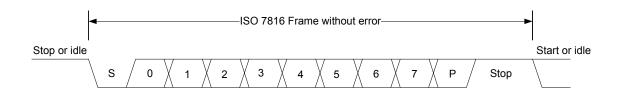

Figure 18.14. USART ISO 7816 Data Frame Without Error

If a parity error is detected by the receiver, it pulls the line I/O line low after half a stop bit, see Figure 18.15 USART ISO 7816 Data Frame With Error on page 568. It holds the line low for one bit-period before it releases the line. In this case, the guard time is extended by one bit period before a new transmission can start, resulting in a total of 3 stop bits.

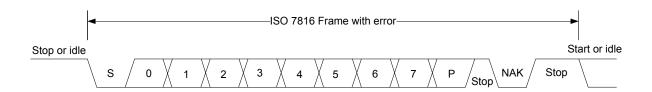

Figure 18.15. USART ISO 7816 Data Frame With Error

On a parity error, the NAK is generated by hardware. The NAK generated by the receiver is sampled as the stop-bit of the frame. Because of this, parity errors when in SmartCard mode are reported with both a parity error and a framing error.

When transmitting a T0 frame, the USART receiver on the transmitting side samples position 16, 17 and 18 in the stop-bit to detect the error signal when in 16x oversampling mode as shown in Figure 18.16 USART SmartCard Stop Bit Sampling on page 569. Sampling at this location places the stop-bit sample in the middle of the bit-period used for the error signal (NAK).

If a NAK is transmitted by the receiver, it will thus appear as a framing error at the transmitter, and the FERR interrupt flag in USARTn_IF will be set. If SCRETRANS USARTn_CTRL is set, the transmitter will automatically retransmit a NACK'ed frame. The transmitter will retransmit the frame until it is ACK'ed by the receiver. This only works when the number of databits in a frame is configured to 8.

Set SKIPPERRF in USARTn_CTRL to make the receiver discard frames with parity errors. The PERR interrupt flag in USARTn_IF is set when a frame is discarded because of a parity error.

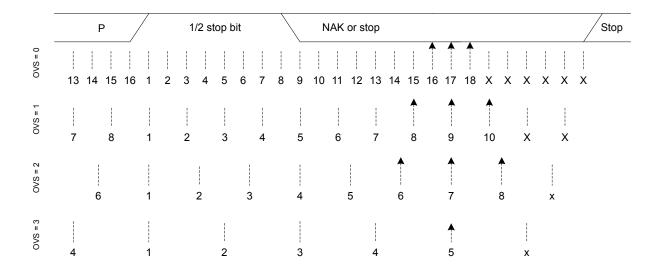

Figure 18.16. USART SmartCard Stop Bit Sampling

For communication with a SmartCard, a clock signal needs to be generated for the card. This clock output can be generated using one of the timers. See the ISO 7816 specification for more info on this clock signal.

SmartCard T1 mode is also supported. The T1 frame format used is the same as the asynchronous frame format with parity bit enabled and one stop bit. The USART must then be configured to operate in asynchronous half duplex mode.

# 18.3.3 Synchronous Operation

Most of the features in asynchronous mode are available in synchronous mode. Multi-processor mode can be enabled for 9-bit frames, loopback is available and collision detection can be performed.

# 18.3.3.1 Frame Format

The frames used in synchronous mode need no start and stop bits since a single clock is available to all parts participating in the communication. Parity bits cannot be used in synchronous mode.

The USART supports frame lengths of 4 to 16 bits per frame. Larger frames can be simulated by transmitting multiple smaller frames, i.e. a 22 bit frame can be sent using two 11-bit frames, and a 21 bit frame can be generated by transmitting three 7-bit frames. The number of bits in a frame is set using DATABITS in USARTn_FRAME.

The frames in synchronous mode are by default transmitted with the least significant bit first like in asynchronous mode. The bit-order can be reversed by setting MSBF in USARTn CTRL.

The frame format used by the transmitter can be inverted by setting TXINV in USARTn_CTRL, and the format expected by the receiver can be inverted by setting RXINV, also in USARTn_CTRL.

#### 18.3.3.2 Clock Generation

The bit-rate in synchronous mode is given by Figure 18.17 USART Synchronous Mode Bit Rate on page 570. As in the case of asynchronous operation, the clock division factor have a 15-bit integral part and a 5-bit fractional part.

$$br = f_{HFPERCLK}/(2 x (1 + USARTn_CLKDIV/256))$$

Figure 18.17. USART Synchronous Mode Bit Rate

Given a desired baud rate brdesired, the clock divider USARTn_CLKDIV can be calculated using Figure 18.18 USART Synchronous Mode Clock Division Factor on page 570

$$USARTn_CLKDIV = 256 \times (f_{HFPERCLK}/(2 \times brdesired) - 1)$$

Figure 18.18. USART Synchronous Mode Clock Division Factor

When the USART operates in master mode, the highest possible bit rate is half the peripheral clock rate. When operating in slave mode however, the highest bit rate is an eighth of the peripheral clock:

- Master mode: br_{max} = f_{HFPERCLK}/2
- Slave mode: br_{max} = f_{HFPERCLK}/8

On every clock edge data on the data lines, MOSI and MISO, is either set up or sampled. When CLKPHA in USARTn_CTRL is cleared, data is sampled on the leading clock edge and set-up is done on the trailing edge. If CLKPHA is set however, data is set-up on the leading clock edge, and sampled on the trailing edge. In addition to this, the polarity of the clock signal can be changed by setting CLKPOL in USARTn_CTRL, which also defines the idle state of the clock. This results in four different modes which are summarized in Table 18.8 USART SPI Modes on page 570. Figure 18.19 USART SPI Timing on page 570 shows the resulting timing of data set-up and sampling relative to the bus clock.

SPI mode **CLKPOL CLKPHA** Leading Edge **Trailing Edge** 0 0 0 Rising, sample Falling, set-up 0 1 1 Rising, set-up Falling, sample 1 0 2 Falling, sample Rising, set-up 3 1 1 Falling, set-up Rising, sample

Table 18.8. USART SPI Modes

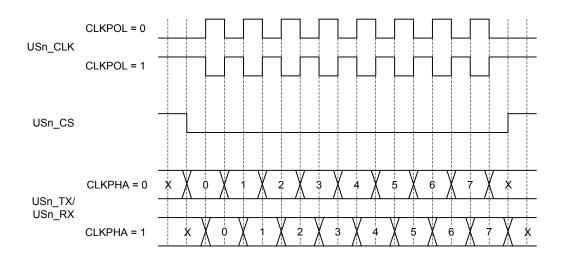

Figure 18.19. USART SPI Timing

If CPHA=1, the TX underflow flag, TXUF, will be set on the first setup clock edge of a frame in slave mode if TX data is not available. If CPHA=0, TXUF is set if data is not available in the transmit buffer three HFPERCLK cycles prior to the first sample clock edge. The

RXDATAV flag is updated on the last sample clock edge of a transfer, while the RX overflow interrupt flag, RXOF, is set on the first sample clock edge if the receive buffer overflows. When a transfer has been performed, interrupt flags TXBL and TXC are updated on the first setup clock edge of the succeeding frame, or when CS is deasserted.

#### 18.3.3.3 Master Mode

When in master mode, the USART is in full control of the data flow on the synchronous bus. When operating in full duplex mode, the slave cannot transmit data to the master without the master transmitting to the slave. The master outputs the bus clock on USn_CLK.

Communication starts whenever there is data in the transmit buffer and the transmitter is enabled. The USART clock then starts, and the master shifts bits out from the transmit shift register using the internal clock.

When there are no more frames in the transmit buffer and the transmit shift register is empty, the clock stops, and communication ends. When the receiver is enabled, it samples data using the internal clock when the transmitter transmits data. Operation of the RX and TX buffers is as in asynchronous mode.

### 18.3.3.4 Operation of USn_CS Pin

When operating in master mode, the USn CS pin can have one of two functions, or it can be disabled.

If USn_CS is configured as an output, it can be used to automatically generate a chip select for a slave by setting AUTOCS in USARTn_CTRL. If AUTOCS is set, USn_CS is activated before a transmission begins, and deactivated after the last bit has been transmitted and there is no more data in the transmit buffer.

The time between when CS is asserted and the first bit is transmitted can be controlled using the USART Timer and with CSSETUP in USARTn_TIMING. Any of the three comparators can be used to set this delay. If new data is ready for transmission before CS is deas-serted, the data is sent without deasserting CS in between. CSHOLD in USARTn_TIMING keeps CS asserted after the end of frame for the number of baud-times specified.

By default, USn CS is active low, but its polarity can be inverted by setting CSINV in USARTn CTRL.

When USn_CS is configured as an input, it can be used by another master that wants control of the bus to make the USART release it. When USn_CS is driven low, or high if CSINV is set, the interrupt flag SSM in USARTn_IF is set, and if CSMA in USARTn_CTRL is set, the USART goes to slave mode.

### 18.3.3.5 AUTOTX

A synchronous master is required to transmit data to a slave in order to receive data from the slave. In some cases, only a few words are transmitted and a lot of data is then received from the slave. In that case, one solution is to keep feeding the TX with data to transmit, but that consumes system bandwidth. Instead AUTOTX can be used.

When AUTOTX in USARTn_CTRL is set, the USART transmits data as long as there is available space in the RX shift register for the chosen frame size. This happens even though there is no data in the TX buffer. The TX underflow interrupt flag TXUF in USARTn_IF is set on the first word that is transmitted which does not contain valid data.

During AUTOTX the USART will always send the previous sent bit, thus reducing the number of transitions on the TX output. So if the last bit sent was a 0, 0's will be sent during AUTOTX and if the last bit sent was a 1, 1's will be sent during AUTOTX.

# 18.3.3.6 Slave Mode

When the USART is in slave mode, data transmission is not controlled by the USART, but by an external master. The USART is therefore not able to initiate a transmission, and has no control over the number of bytes written to the master.

The output and input to the USART are also swapped when in slave mode, making the receiver take its input from USn_TX (MOSI) and the transmitter drive USn_RX (MISO).

To transmit data when in slave mode, the slave must load data into the transmit buffer and enable the transmitter. The data will remain in the USART until the master starts a transmission by pulling the USn_CS input of the slave low and transmitting data. For every frame the master transmits to the slave, a frame is transferred from the slave to the master. After a transmission, MISO remains in the same state as the last bit transmitted. This also applies if the master transmits to the slave and the slave TX buffer is empty.

If the transmitter is enabled in synchronous slave mode and the master starts transmission of a frame, the underflow interrupt flag TXUF in USARTn IF will be set if no data is available for transmission to the master.

If the slave needs to control its own chip select signal, this can be achieved by clearing CSPEN in the ROUTE register. The internal chip select signal can then be controlled through CSINV in the CTRL register. The chip select signal will be CSINV inverted, i.e. if CSINV is cleared, the chip select is active and vice versa.

#### 18.3.3.7 Synchronous Half Duplex Communication

Half duplex communication in synchronous mode is very similar to half duplex communication in asynchronous mode as detailed in 18.3.2.15 Asynchronous Half Duplex Communication. The main difference is that in this mode, the master must generate the bus clock even when it is not transmitting data, i.e. it must provide the slave with a clock to receive data. To generate the bus clock, the master should transmit data with the transmitter tristated, i.e. TXTRI in USARTn_STATUS set, when receiving data. If 2 bytes are expected from the slave, then transmit 2 bytes with the transmitter tristated, and the slave uses the generated bus clock to transmit data to the master. TXTRI can be set by setting the TXTRIEN command bit in USARTn_CMD.

**Note:** When operating as SPI slave in half duplex mode, TX has to be tristated (not disabled) during data reception if the slave is to transmit data in the current transfer.

#### 18.3.3.8 I2S

I2S is a synchronous format for transmission of audio data. The frame format is 32-bit, but since data is always transmitted with MSB first, an I2S device operating with 16-bit audio may choose to only process the 16 msb of the frame, and only transmit data in the 16 msb of the frame.

In addition to the bit clock used for regular synchronous transfers, I2S mode uses a separate word clock. When operating in mono mode, with only one channel of data, the word clock pulses once at the start of each new word. In stereo mode, the word clock toggles at the start of new words, and also gives away whether the transmitted word is for the left or right audio channel; A word transmitted while the word clock is low is for the left channel, and a word transmitted while the word clock is high is for the right.

When operating in I2S mode, the CS pin is used as a the word clock. In master mode, this is automatically driven by the USART, and in slave mode, the word clock is expected from an external master.

#### 18.3.3.9 Word Format

The general I2S word format is 32 bits wide, but the USART also supports 16-bit and 8-bit words. In addition to this, it can be specified how many bits of the word should actually be used by the USART. These parameters are given by FORMAT in USARTn_I2SCTRL.

As an example, configuring FORMAT to using a 32-bit word with 16-bit data will make each word on the I2S bus 32-bits wide, but when receiving data through the USART, only the 16 most significant bits of each word can be read out of the USART. Similarly, only the 16 most significant bits have to be written to the USART when transmitting. The rest of the bits will be transmitted as zeroes.

#### 18.3.3.10 Major Modes

The USART supports a set of different I2S formats as shown in Table 18.9 USART I2S Modes on page 573, but it is not limited to these modes. MONO, JUSTIFY and DELAY in USARTn_I2SCTRL can be mixed and matched to create an appropriate format. MONO enables mono mode, i.e. one data stream instead of two which is the default. JUSTIFY aligns data within a word on the I2S bus, either left or right which can bee seen in figures Figure 18.22 USART Left-Justified I2S Waveform on page 574 and Figure 18.23 USART Right-Justified I2S Waveform on page 574. Finally, DELAY specifies whether a new I2S word should be started directly on the edge of the word-select signal, or one bit-period after the edge.

Table 18.9. USART I2S Modes

Mode	MONO	JUSTIFY	DELAY	CLKPOL
Regular I2S	0	0	1	0
Left-Justified	0	0	0	1
Right-Justified	0	1	0	1
Mono	1	0	0	0

The regular I2S waveform is shown in Figure 18.20 USART Standard I2S Waveform on page 573 and Figure 18.21 USART Standard I2S Waveform (Reduced Accuracy) on page 573. The first figure shows a waveform transmitted with full accuracy. The wordlength can be configured to 32-bit, 16-bit or 8-bit using FORMAT in USARTn_I2SCTRL. In the second figure, I2S data is transmitted with reduced accuracy, i.e. the data transmitted has less bits than what is possible in the bus format.

Note that the msb of a word transmitted in regular I2S mode is delayed by one cycle with respect to word select

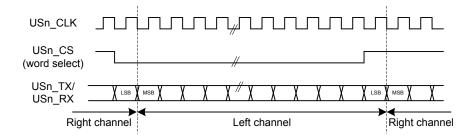

Figure 18.20. USART Standard I2S Waveform

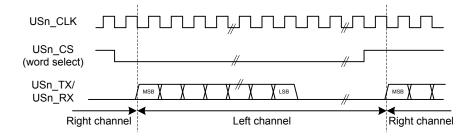

Figure 18.21. USART Standard I2S Waveform (Reduced Accuracy)

A left-justified stream is shown in Figure 18.22 USART Left-Justified I2S Waveform on page 574. Note that the MSB comes directly after the edge on the word-select signal in contradiction to the regular I2S waveform where it comes one bit-period after.

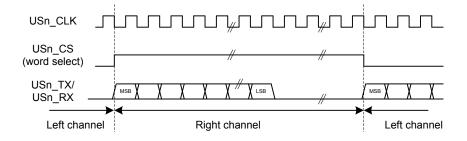

Figure 18.22. USART Left-Justified I2S Waveform

A right-justified stream is shown in Figure 18.23 USART Right-Justified I2S Waveform on page 574. The left and right justified streams are equal when the data-size is equal to the word-width.

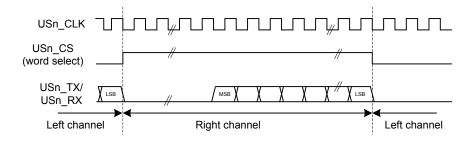

Figure 18.23. USART Right-Justified I2S Waveform

In mono-mode, the word-select signal pulses at the beginning of each word instead of toggling for each word. Mono I2S waveform is shown in Figure 18.24 USART Mono I2S Waveform on page 574.

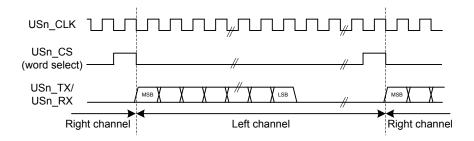

Figure 18.24. USART Mono I2S Waveform

#### 18.3.3.11 Using I2S Mode

When using the USART in I2S mode, DATABITS in USARTn_FRAME must be set to 8 or 16 data-bits. 8 databits can be used in all modes, and 16 can be used in the modes where the number of bytes in the I2S word is even. In addition to this, MSBF in USARTn CTRL should be set, and CLKPOL and CLKPHA in USARTn CTRL should be cleared.

The USART does not have separate TX and RX buffers for left and right data, so when using I2S in stereo mode, the application must keep track of whether the buffers contain left or right data. This can be done by observing TXBLRIGHT, RXDATAVRIGHT and RXFULLRIGHT in USARTn_STATUS. TXBLRIGHT tells whether TX is expecting data for the left or right channel. It will be set with TXBL if right data is expected. The receiver will set RXDATAVRIGHT if there is at least one right element in the buffer, and RXFULL-RIGHT if the buffer is full of right elements.

When using I2S with DMA, separate DMA requests can be used for left and right data by setting DMASPLIT in USARTn I2SCTRL.

In both master and slave mode the USART always starts transmitting on the LEFT channel after being enabled. In master mode, the transmission will stop if TX becomes empty. In that case, TXC is set. Continuing the transmission in this case will make the data-stream continue where it left off. To make the USART start on the LEFT channel after going empty, disable and re-enable TX.

# 18.3.4 Hardware Flow Control

Hardware flow control can be used to hold off the link partner's transmission until RX buffer space is available. Use RTSPEN and CTSPEN in USARTn_ROUTEPEN to allocate the hardware flow control to GPlOs. RTS is an out going signal which indicates that RX buffer space is available to receive a frame. The link partner is being requested to send its data when RTS is asserted. CTS is an incoming signal to stop the next TX data from going out. When CTS is negated, the frame currently being transmitted is completed before stopping. CTS indicates that the link partner has RX buffer space available, and the local transmitter is clear to send. Also use CTSEN in USARTn_CTLX to enable the CTS input into the TX sequencer. For debug use set DBGHALT in USARTn_CTRLX which will force the RTS to request one frame from the link partner when the CPU core single steps.

### 18.3.5 Debug Halt

When DBGHALT in USART_CTRLX is clear, RTS is only dependent on the RX buffer having space available to receive data. Incoming data is always received until both the RX buffer is full and the RX shift register is full regardless of the state of DBGHALT or chip halt. Additional incoming data is discarded. When DBGHALT is set, RTS deasserts on RX buffer full or when chip halt is high. However, a low pulse detected on chip halt will keep RTS asserted when no frame is being received. At the start of frame reception, RTS will deassert if chip halt is high and DBGHALT is set. This behavior allows single stepping to pulse the chip halt low for a cycle, and receive the next frame. The link partner must stop transmitting when RTS is deasserted, or the RX buffer could overflow. All data in the transmit buffer is sent out even when chip halt is asserted; therefore, the DMA will need to be set to stop sending the USART TX data during chip halt.

### 18.3.6 PRS-triggered Transmissions

If a transmission must be started on an event with very little delay, the PRS system can be used to trigger the transmission. The PRS channel to use as a trigger can be selected using TSEL in USARTn_TRIGCTRL. When a positive edge is detected on this signal, the receiver is enabled if RXTEN in USARTn_TRIGCTRL is set, and the transmitter is enabled if TXTEN in USARTn_TRIGCTRL is set. Only one signal input is supported by the USART.

The AUTOTX feature can also be enabled via PRS. If an external SPI device sets a pin high when there is data to be read from the device, this signal can be routed to the USART through the PRS system and be used to make the USART clock data out of the external device. If AUTOTXTEN in USARTn_TRIGCTRL is set, the USART will transmit data whenever the PRS signal selected by TSEL is high given that there is enough room in the RX buffer for the chosen frame size. Note that if there is no data in the TX buffer when using AUTOTX, the TX underflow interrupt will be set.

AUTOTXTEN can also be combined with TXTEN to make the USART transmit a command to the external device prior to clocking out data. To do this, disable TX using the TXDIS command, load the TX buffer with the command and enable AUTOTXTEN and TXTEN. When the selected PRS input goes high, the USART will now transmit the loaded command, and then continue clocking out while both the PRS input is high and there is room in the RX buffer

#### 18.3.7 PRS RX Input

The USART can be configured to receive data directly from a PRS channel by setting RXPRS in USARTn_INPUT. The PRS channel used is selected using RXPRSSEL in USARTn_INPUT. This way, for example, a differential RX signal can be input to the ACMP and the output routed via PRS to the USART.

#### 18.3.8 PRS CLK Input

The USART can be configured to receive clock directly from a PRS channel by setting CLKPRS in USARTn_INPUT. The PRS channel used is selected using CLKPRSSEL in USARTn_INPUT. This is useful in synchronous slave mode and can together with RX PRS input be used to input data from PRS.

# 18.3.9 DMA Support

The USART has full DMA support. The DMA controller can write to the transmit buffer using the registers USARTn_TXDATA, USARTn_TXDOUBLE and USARTn_TXDOUBLEX, and it can read from the receive buffer using the registers USARTn_RXDATA, USARTn_RXDATAX, USARTn_RXDOUBLE and USARTn_RXDOUBLEX. This enables single byte transfers, 9 bit data + control/status bits, double byte and double byte + control/status transfers both to and from the USART.

A request for the DMA controller to read from the USART receive buffer can come from the following source:

- · Data available in the receive buffer
- Data available in the receive buffer and data is for the RIGHT I2S channel. Only used in I2S mode.

A write request can come from one of the following sources:

- Transmit buffer and shift register empty. No data to send.
- Transmit buffer has room for more data. This does not check the TXBIL for half full. For DMA use, it is either full or empty.
- · Transmit buffer has room for RIGHT I2S data. Only used in I2S mode

Even though there are two sources for write requests to the DMA, only one should be used at a time, since the requests from both sources are cleared even though only one of the requests are used.

In some cases, it may be sensible to temporarily stop DMA access to the USART when an error such as a framing error has occurred. This is enabled by setting ERRSDMA in USARTn CTRL.

For Synchronous mode full duplex operation, if both receive buffer and transmit buffer are served by DMA, to make sure receive buffer is not overflowed the settings below should be followed.

- The DMA channel that serves receive buffer should have higher priority than the DMA channel that serves transmit buffer.
- TXBL should be used as write request for transmit buffer DMA channel.
- IGNORESREQ should be set for both DMA channel.

#### 18.3.10 Timer

In addition to the TX sequence timer, there is a versatile 8 bit timer that can generate up to three event pulses. These pulses can be used to create timing for a variety of uses such as RX timeout, break detection, response timeout, and RX enable delay. Transmission delay, CS setup, inter-character spacing, and CS hold use the TX sequence counter. The TX sequencer counter can use the three 8 bit compare values or preset values for delays. There is one general counter with three comparators. Each comparator has a start source, a stop source, a restart enable, and a timer compare value. The start source enables the comparator, resets the counter, and starts the counter. If the counter is already running, the start source will reset the counter and restart it.

Any comparator could start the counter using the same start source but have different timing events programmed into TCMPVALn in USARTn_TIMECMPn. The TCMP0, TCMP1, or TCMP2 events can be preempted by using the comparator stop source to disable the comparator before the counter reaches TCMPVAL0, TCMPVAL1, or TCMPVAL2. If one comparator gets disabled while the other comparator is still enabled, the counter continues counting. By default the counter will count up to 256 and stop unless a RESTARTEN is set in one of the USARTn_TIMECMPn registers. By using RESTARTEN and an interval programmed into TCMPVAL, an interval timer can be set up. The TSTART field needs to be changed to DISABLE to stop the interval timer. The timer stops running once all of the comparators are disabled. If a comparator's start and stop sources both trigger the same cycle, the TCMPn event triggers, the comparator stays enabled, and the counter begins counting from zero.

The TXDELAY, CSSETUP, ICS, and CSHOLD in USARTn_TIMING are used to program start of transmission delay, chip select setup delay, inter-character space, and chip select hold delay. Either a preset value of 0, 1, 2, 3, or 7 can be used for any of these delays; or the value in TCMPVALn may be used to set the delay. Using the preset values leaves the TCMPVALn free for other uses. The same TCMPVALn may be used for multiple events that require the same timing. The transmit sequencer's counter can run in parallel with the timer's counter. The counters and controls are shown in Figure 18.25 USART Timer Block Diagram on page 578.

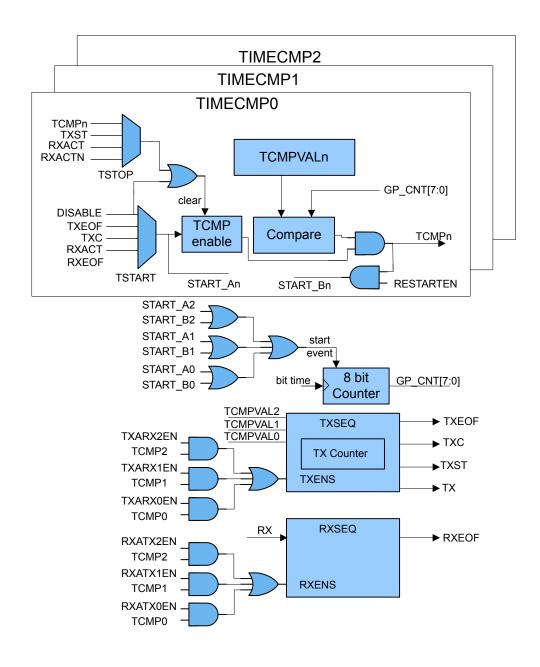

Figure 18.25. USART Timer Block Diagram

The following sections will go into more details on programming the various usage cases.

Table 18.10. USART Application Settings for USARTn_TIMING and USARTn_TIMECMPn

Application	TSTARTn	TSTOPn	TCMPVALn	Other
Response Timeout	TSTART0 = TXEOF	TSTOP0 = RXACT	TCMPVAL0 = 0x08	TCMP0 in USARTn_IEN
Receiver Timeout	TSTART1 = RXEOF	TSTOP1 = RXACT	TCMPVAL1 = 0x08	TCMP1 in USARTn_IEN
Large Receiver Timeout	TSTART1 = RXEOF, TCMP1	TSTOP1 = RXACT	TCMPVAL1 = 0xFF	TCMP1 in USARTn_IEN; TIME- RRESTARTED in USARTn_STA- TUS; RESTART1EN in USARTn_TIMECMP1

Application	TSTARTn	TSTOPn	TCMPVALn	Other
Break Detect	TSTART1 = RXACT	TSTOP1 = RXACTN	TCMPVAL1 = 0x0C	TCMP1 in USARTn_IEN
TX delayed start of transmission and CS setup	TSTART0 = DISA- BLE, TSTART1 = DISABLE	TSTOP0 = TCMP0, TSTOP1 = TCMP1	TCMPVAL0 = 0x04, TCMPVAL1 = 0x02	TXDELAY = TCMP0, CSSETUP = TCMP1 in USARTn_TIMING; AUTOCS in USARTn_CTRL
TX inter-character spacing	TSTART2 = DISA- BLE	TSTOP2 = TCMP2	TCMPVAL2 = 0x03	ICS = TCMP2 in USARTn_TIMING; AUTOCS in USARTn_CTRL
TX Chip Select End Delay	TSTART1 = DISA- BLE	TSTOP1 = TCMP1	TCMPVAL1 = 0x04	CSHOLD = TCMP1 in USARTn_TIMING; AUTOCS in USARTn_CTRL
Response Delay	TSTART1 = RXEOF	TSTOP1 = TCMP1	TCMPVAL1 = 0x08	TXARX1EN in USARTn_TRIGCTRL
Combined TX and RX Example	TSTART1 = RXEOF, TSTART0 = TXEOF	TSTOP1 = TCMP1, TSTOP0 = TCMP0	TCMPVAL1 = 0x1C, TCMPVAL0 = 0x10	TXARX1EN, RXATX0EN in USARTn_TRIGCTRL; CSSETUP = 0x7, CSHOLD = 0x3 in USARTn_TIMING
Combined Delayed TX and Receiver Timeout Example	TSTART0 = TCMPVAL0, TSTART1 = RXEOF	TSTOP0 = RXACTN, TSTOP1 = RXACT	TCMPVAL0 = 0x20, TCMPVAL1 = 0x0C	TXARX0EN in USARTn_TRIGCTRL; TCMP0 in USARTn_IEN

Table 18.10 USART Application Settings for USARTn_TIMING and USARTn_TIMECMPn on page 578 shows some examples of how the USART timer can be programmed for various applications. The following sections will describe more details for each applications shown in the table.

#### 18.3.10.1 Response Timeout

Response Timeout is when a UART master sends a frame and expects the slave to respond within a certain number of baud-times. Refer to Table 18.10 USART Application Settings for USARTn_TIMING and USARTn_TIMECMPn on page 578 for specific register settings. Comparator 0 will be looking for TX end of frame to use as the timer start source. For this example, a receiver start of frame RXACT has not been detected for 8 baud-times, and the TCMP0 interrupt in USARTn_IF is set. If an RX start bit is detected before the 8 baud-times, comparator 0 is disabled before the TCMP0 event can trigger.

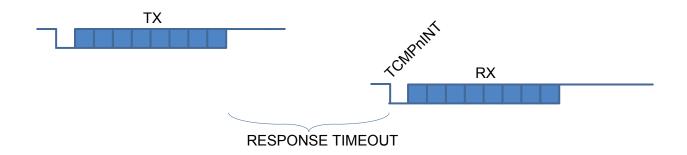

Figure 18.26. USART Response Timeout

#### 18.3.10.2 RX Timeout

A receiver timeout function can be implemented by using the RX end of frame to start comparator 1 and look for the RX start bit RXACT to disable the comparator. See Table 18.10 USART Application Settings for USARTn_TIMING and USARTn_TIMECMPn on page 578 for details on setting up this example. As long as the next RX start bit occurs before the counter reaches the comparator 1 value TCMPVAL1, the interrupt will not get set. In this example the RX Timeout was set to 8 baud-times. To get an RX timeout larger than 256 baud-times, RESTART1EN in USARTn_TIMER can used to restart the counter when it reaches TCMPVAL1. By setting TCMPVAL1 in USARTn_TIMING to 0xFF, an interrupt will be generated after 256 baud-times. An interrupt service routine can then increment a memory location until the desired timeout is reached. Once the RX start bit is detected, comparator 1 will be disabled. If TIMERRESTARTED in USARTn_STATUS is clear, the TCMP1 interrupt is the first interrupt after RXEOF.

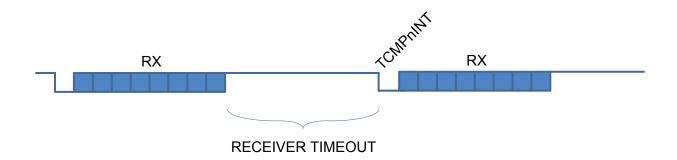

Figure 18.27. USART RX Timeout

#### 18.3.10.3 Break Detect

LIN bus and half-duplex UARTs can take advantage of the timer configured for break detection where RX is held low for a number of baud-times to indicate a break condition. Table 18.10 USART Application Settings for USARTn_TIMING and USARTn_TIMECMPn on page 578 shows the settings for this mode. Each time RX is active (default of low) such as for a start bit, the timer begins counting. If the counter reaches 12 baud-times before RX goes to inactive RXACTN (default of high), an interrupt is asserted.

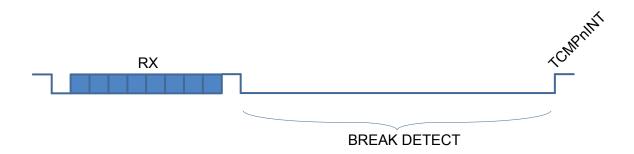

Figure 18.28. USART Break Detection

#### 18.3.10.4 TX Start Delay

Some applications may require a delay before the start of transmission. This example in Figure 18.29 USART TXSEQ Timing on page 581 shows the TXSEQ timer used to delay the start of transmission by 4 baud times before the start of CS, and by 2 baud times with CS asserted. See Table 18.10 USART Application Settings for USARTn_TIMING and USARTn_TIMECMPn on page 578 for details on how to configure this mode. The TX sequencer could be enabled on PRS and start the TXSEQ counter running for 4 baud times as programmed in TCMPVAL0. Then CS is asserted for 2 baud times before the transmitter begins sending TX data. TXDELAY in USARTn_TIMING is the initial delay before any CS assertion, and CSSETUP is the delay during CS assertion. There are several small preset timing values such as 1, 2, 3, or 7 that can be used for some of the TX sequencer timing which leaves TCMPVAL0, TCMPVAL1, and TCMPVAL2 free for other uses.

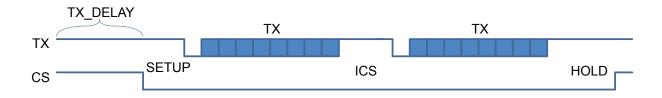

Figure 18.29. USART TXSEQ Timing

#### 18.3.10.5 Inter-Character Space

In addition to delaying the start of frame transmission, it is sometimes necessary to also delay the time between each transmit character (inter-character space). After the first transmission, the inter-character space will delay the start of all subsequent transmissions until the transmit buffer is empty. See Table 18.10 USART Application Settings for USARTn_TIMING and USARTn_TIMECMPn on page 578 for details on setting up this example. For this example in Figure 18.29 USART TXSEQ Timing on page 581 ICS is set to TCMP2 in USARTn_TIMING. To keep CS asserted during the inter-character space, set AUTOCS in USARTn_CTRL. There are a few small preset timing values provided for TX sequence timing. Using these preset timing values can free up the TCMPVALn for other uses. For this example, the inter-character space is set to 0x03 and a preset value could be used.

#### 18.3.10.6 TX Chip Select End Delay

The assertion of CS can be extended after the final character of the frame by using CSHOLD in USARTn_TIMING. See Table 18.10 USART Application Settings for USARTn_TIMING and USARTn_TIMECMPn on page 578 for details on setting up this example. AUTOCS in USARTn_CTRL needs to be set to extend the CS assertion after the last TX character is transmitted as shown in Figure 18.29 USART TXSEQ Timing on page 581.

#### 18.3.10.7 Response Delay

A response delay can be used to hold off the transmitter until a certain number of baud-times after the RX frame. See Table 18.10 USART Application Settings for USARTn_TIMING and USARTn_TIMECMPn on page 578 for details on setting up this example. TXARX1EN in USARTn_TRIGCTRL tells the TX sequencer to trigger after RX EOF plus tcmp1val baud times.

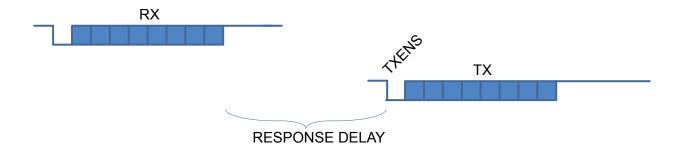

Figure 18.30. USART Response Delay

#### 18.3.10.8 Combined TX and RX Example

This example describes how to alternate between TX and RX frames. This has a 28 baud-time space after RX and a 16 baud-time space after TX. The TSTART1 in USARTn_TIMECMP1 is set to RXEOF which uses the the receiver end of frame to start the timer. The TSTOP1 is set to TCMP1 to generate an event after 28 baud times. Set TXARX1EN in USARTn_TRIGCTRL, and the transmitter is held off until 28 baud times. TCMPVAL in USARTn_TIMECMP1 is set to 0x1C for 28 baud times. By setting TSTART0 in USARTn_TIMECMP0 to TXEOF, the timer will be started after the transmission has completed. RXATX0EN in USARTn_TRIGCTRL is used to delay enabling of the receiver until 16 baud times after the transmitter has completed. Write 0x10 into TCMPVAL of USARTn_TIMECMP0 for a 16 baud time delay. CS is also asserted 7 baud-times before start of transmission by setting CSSETUP to 0x7 in USARTn_TIMING. To keep CS asserted for 3 baud-times after transmission completes, CSHOLD is set to 0x3 in USARTn_TIMING. See Table 18.10 USART Application Settings for USARTn_TIMING and USARTn_TIMECMPn on page 578 for details on setting up this example.

#### 18.3.10.9 Combined TX Delay and RX Break Detect

This example describes how to delay TX transmission after an RX frame and how to have a break condition signal an interrupt. See Table 18.10 USART Application Settings for USARTn_TIMING and USARTn_TIMECMPn on page 578 for details on setting up this example. The TX delay is set up by using transmit after RX, TXARX0EN in USARTn_TRIGCTRL to start the timer. TSTART0 in USARTn_TIMECMP0 is set to RXEOF which enables the transitter of the timer delay. For this example TCMPVAL in USARTn_TIMECMP0 is set to 0x20 to create a 32 baud-time delay between the end of the RX frame and the start of the TX frame. The break detect is configured by setting TSTART1 to RXACT to detect the start bit, and setting TSTOP1 to RXACTN to detect RX going high. In this case the interrupt asserts after RX stays low for 12 baud-times, so TCMPVAL1 is set to 0x0C.

#### 18.3.10.10 Other Stop Conditions

There is also a timer stop on TX start using the TXST setting in TSTOP of USARTn_TIMECMPn. This can be used to see that the DMA has not written to the TXBUFFER for a given time.

#### 18.3.11 Interrupts

The interrupts generated by the USART are combined into two interrupt vectors. Interrupts related to reception are assigned to one interrupt vector, and interrupts related to transmission are assigned to the other. Separating the interrupts in this way allows different priorities to be set for transmission and reception interrupts.

The transmission interrupt vector groups the transmission-related interrupts generated by the following interrupt flags:

- TXC
- TXBL
- TXOF
- CCF
- TXIDLE

The reception interrupt on the other hand groups the reception-related interrupts, triggered by the following interrupt flags:

- RXDATAV
- RXFULL
- RXOF
- RXUF
- PERR
- FERR
- MPAF
- SSM
- TCMPn

If USART interrupts are enabled, an interrupt will be made if one or more of the interrupt flags in USART_IF and their corresponding bits in USART_IEN are set.

#### 18.3.12 IrDA Modulator/ Demodulator

The IrDA modulator implements the physical layer of the IrDA specification, which is necessary for communication over IrDA. The modulator takes the signal output from the USART module, and modulates it before it leaves the USART. In the same way, the input signal is demodulated before it enters the actual USART module. The modulator implements the original Rev. 1.0 physical layer and one high speed extension which supports speeds from 2.4 kbps to 1.152 Mbps.

The data from and to the USART is represented in a NRZ (Non Return to Zero) format, where the signal value is at the same level through the entire bit period. For IrDA, the required format is RZI (Return to Zero Inverted), a format where a "1" is signalled by holding the line low, and a "0" is signalled by a short high pulse. An example is given in Figure 18.31 USART Example RZI Signal for a given Asynchronous USART Frame on page 583.

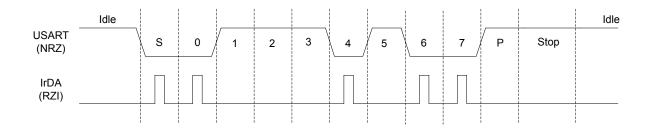

Figure 18.31. USART Example RZI Signal for a given Asynchronous USART Frame

The IrDA module is enabled by setting IREN. The USART transmitter output and receiver input is then routed through the IrDA modulator.

The width of the pulses generated by the IrDA modulator is set by configuring IRPW in USARTn_IRCTRL. Four pulse widths are available, each defined relative to the configured bit period as listed in Table 18.11 USART IrDA Pulse Widths on page 583.

IRPW	Pulse width OVS=0	Pulse width OVS=1	Pulse width OVS=2	Pulse width OVS=3
00	1/16	1/8	1/6	1/4
01	2/16	2/8	2/6	N/A
10	3/16	3/8	N/A	N/A
11	4/16	N/A	N/A	N/A

Table 18.11. USART IrDA Pulse Widths

By default, no filter is enabled in the IrDA demodulator. A filter can be enabled by setting IRFILT in USARTn_IRCTRL. When the filter is enabled, an incoming pulse has to last for 4 consecutive clock cycles to be detected by the IrDA demodulator.

Note that by default, the idle value of the USART data signal is high. This means that the IrDA modulator generates negative pulses, and the IrDA demodulator expects negative pulses. To make the IrDA module use RZI signalling, both TXINV and RXINV in USARTn_CTRL must be set.

The IrDA module can also modulate a signal from the PRS system, and transmit a modulated signal to the PRS system. To use a PRS channel as transmitter source instead of the USART, set IRPRSEN in USARTn_IRCTRL high. The channel is selected by configuring IRPRSSEL in USARTn_IRCTRL.

## 18.4 Register Map

The offset register address is relative to the registers base address.

Offset	Name	Туре	Description

31:17	Reserved	To ensure o	compatibility	with future devices, always write bits to 0. More information in 1.2 Conven-
16	TCMP2	0	R	Timer Comparator 2 Interrupt Flag
	Set when the time	er reaches the co	mparator 2 va	alue, TCMP2.
15	TCMP1	0	R	Timer Comparator 1 Interrupt Flag
	Set when the time	er reaches the co	mparator 1 va	alue, TCMP1.
14	TCMP0	0	R	Timer Comparator 0 Interrupt Flag
	Set when the Tim	ner reaches the co	mparator 0 v	value, TCMP0.
13	TXIDLE	0	R	TX Idle Interrupt Flag
	Set when TX goe	es idle. At this poin	nt, transmissio	on has ended
12	CCF	0	R	Collision Check Fail Interrupt Flag
	Set when a collis	ion check notices	an error in th	e transmitted data.
11	SSM	0	R	Slave-Select in Master Mode Interrupt Flag
	Set when the dev	vice is selected as	a slave wher	n in master mode.
10	MPAF	0	R	Multi-Processor Address Frame Interrupt Flag
	Set when a multi-	-processor addres	s frame is de	etected.
9	FERR	0	R	Framing Error Interrupt Flag
	Set when a frame	e with a framing e	rror is receive	ed while RXBLOCK is cleared.
8	PERR	0	R	Parity Error Interrupt Flag
	Set when a frame	e with a parity erro	or (asynchron	ous mode only) is received while RXBLOCK is cleared.
7	TXUF	0	R	TX Underflow Interrupt Flag
	Set when operati of a new frame.	ng as a synchrono	ous slave, no	data is available in the transmit buffer when the master starts transmission
6	TXOF	0	R	TX Overflow Interrupt Flag
	Set when a write	is done to the tran	nsmit buffer v	while it is full. The data already in the transmit buffer is preserved.
5	RXUF	0	R	RX Underflow Interrupt Flag
	Set when trying t	o read from the re	ceive buffer v	when it is empty.
4	RXOF	0	R	RX Overflow Interrupt Flag
	Set when data is	incoming while th	e receive shi	ft register is full. The data previously in the shift register is lost.

Bit	Name	Reset	Access	Description
3	RXFULL	0	R	RX Buffer Full Interrupt Flag
	Set when the rec	eive buffer becom	es full.	
2	RXDATAV	0	R	RX Data Valid Interrupt Flag
	Set when data be	ecomes available i	in the receive	buffer.
1	TXBL	1	R	TX Buffer Level Interrupt Flag
	Set when buffer the fied buffer level.	becomes empty if	buffer level is	s set to 0x0, or when the number of empty TX buffer elements equals speci-
0	TXC	0	R	TX Complete Interrupt Flag
	This interrupt is s	set after a transmis	ssion when bo	oth the TX buffer and shift register are empty.

# 19. LEUART - Low Energy Universal Asynchronous Receiver/Transmitter

#### **Quick Facts**

#### What?

The LEUART provides full UART communication using a low frequency 32.768 kHz clock, and has special features for communication without CPU intervention.

#### Why?

It allows UART communication to be performed in low energy modes, using only a few  $\mu A$  during active communication and only 150 nA when waiting for incoming data.

## How?

A low frequency clock signal allows communication with less energy. Using DMA, the LEUART can transmit and receive data with minimal CPU intervention. Special UART-frames can be configured to help control the data flow, further automating data transmission.

#### 19.1 Introduction

The unique Low Energy UART (LEUART) is a UART that allows two-way UART communication on a strict power budget. Only a 32.768 kHz clock is needed to allow UART communication up to 9600 baud.

Even when the system is in low energy mode EM2 Deep Sleep (with most core functionality turned off), the LEUART can wait for an incoming UART frame while having an extremely low energy consumption. When a UART frame is completely received, the CPU can quickly be woken up. Alternatively, multiple frames can be transferred via the Direct Memory Access (DMA) module into RAM memory before waking up the CPU.

Received data can optionally be blocked until a configurable start frame is detected. A signal frame can be configured to generate an interrupt indicating the end of a data transmission. The start frame and signal frame can be used in combination to handle higher level communication protocols.

Similarly, data can be transmitted in EM2 Deep Sleep either on a frame-by-frame basis with data from the CPU or through use of the DMA.

The LEUART includes all necessary hardware support to make asynchronous serial communication possible with minimal software overhead and low energy consumption.

#### 19.2 Features

- · Low energy asynchronous serial communications
- · Full/half duplex communication
- · Separate TX / RX enable
- · Separate double buffered transmit buffer and receive buffer
- · Programmable baud rate, generated as a fractional division of the LFBCLK
  - · Supports baud rates from 300 baud to 9600 baud
- · Can use a high frequency clock source for even higher baud rates
- Configurable number of data bits: 8 or 9 (plus parity bit, if enabled)
- · Configurable parity: off, even or odd
  - · HW parity bit generation and check
- · Configurable number of stop bits, 1 or 2
- · Capable of sleep-mode wake-up on received frame
  - · Either wake-up on any received byte or
  - · Wake up only on specified start and signal frames
- · Supports transmission and reception in EM0 Active, EM1 Sleep and EM2 Deep Sleep with
  - Full DMA support
  - · Specified start-frame can start reception automatically
- IrDA modulator (pulse generator, pulse extender)
- · Multi-processor mode
- · Loopback mode
  - · Half duplex communication
  - · Communication debugging
- · PRS RX input

# 19.3 Functional Description

An overview of the LEUART module is shown in Figure 19.1 LEUART Overview on page 640.

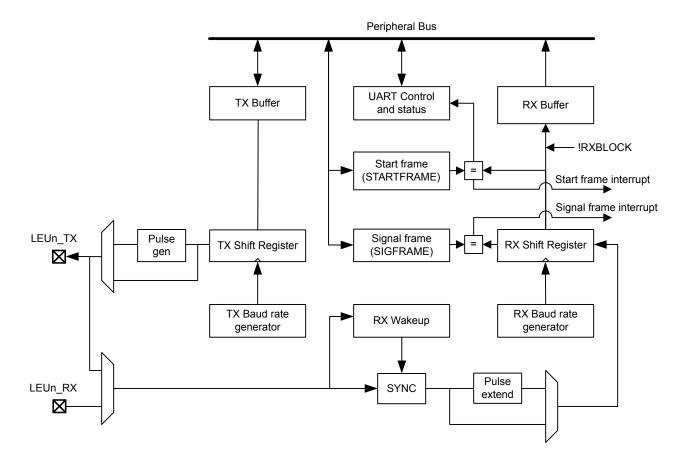

Figure 19.1. LEUART Overview

#### 19.3.1 Frame Format

The frame format used by the LEUART consists of a set of data bits in addition to bits for synchronization and optionally a parity bit for error checking. A frame starts with one start-bit (S), where the line is driven low for one bit-period. This signals the start of a frame, and is used for synchronization. Following the start bit are 8 or 9 data bits and an optional parity bit. The data is transmitted with the least significant bit first. Finally, a number of stop-bits, where the line is driven high, end the frame. The frame format is shown in Figure 19.2 LEUART Asynchronous Frame Format on page 641.

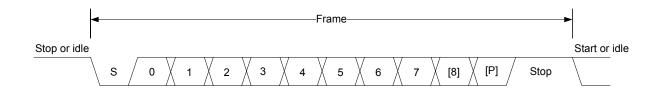

Figure 19.2. LEUART Asynchronous Frame Format

The number of data bits in a frame is set by DATABITS in LEUARTn_CTRL, and the number of stop-bits is set by STOPBITS in LEUARTn_CTRL. Whether or not a parity bit should be included, and whether it should be even or odd is defined by PARITY in LEUARTn_CTRL. For communication to be possible, all parties of an asynchronous transfer must agree on the frame format being used.

The frame format used by the LEUART can be inverted by setting INV in LEUARTn_CTRL. This affects the entire frame, resulting in a low idle state, a high start-bit, inverted data and parity bits, and low stop-bits. INV should only be changed while the receiver is disabled.

# 19.3.1.1 Parity Bit Calculation and Handling

Hardware automatically inserts parity bits into outgoing frames and checks the parity bits of incoming frames. The possible parity modes are defined in Table 19.1 LEUART Parity Bit on page 641. When even parity is chosen, a parity bit is inserted to make the number of high bits (data + parity) even. If odd parity is chosen, the parity bit makes the total number of high bits odd. When parity bits are disabled, which is the default configuration, the parity bit is omitted.

PARITY [1:0] Description

No parity (default)

Reserved

Even parity

Odd parity

Table 19.1. LEUART Parity Bit

See 19.3.5.4 Parity Error for more information on parity bit handling.

## 19.3.2 Clock Source

11

The LEUART clock source is selected by the LFB bit field the CMU_LFBCLKSEL register. The clock is prescaled by the LEUARTn bitfield in the CMU_LFBPRESC0 register and enabled by the LEUARTn bit in the CMU_LFBCLKEN0. See Figure 11.2 CMU Overview - Low Frequency Portion on page 302 for a diagram of the clocking structure.

To use this module, the LE interface clock must be enabled in CMU_HFBUSCLKEN0, in addition to the module clock.

#### 19.3.3 Clock Generation

The LEUART clock defines the transmission and reception data rate. The clock generator employs a fractional clock divider to allow baud rates that are not attainable by integral division of the 32.768 kHz clock that drives the LEUART.

The clock divider used in the LEUART is a 14-bit value, with a 9-bit integral part and a 5-bit fractional part. The baud rate of the LEUART is given by:

br = fLEUARTn / (1 + LEUARTn CLKDIV / 256)

# Figure 19.3. LEUART Baud Rate Equation

where fLEUARTn is the clock frequency supplied to the LEUART. The value of LEUARTn_CLKDIV thus defines the baud rate of the LEUART. The integral part of the divider is right-aligned in the upper 24 bits of LEUARTn_CLKDIV and the fractional part is left-aligned in the lower 8 bits. The divider is thus a 256th of LEUARTn_CLKDIV as seen in the equation.

As an example let us assume fLEUART = 22.5 kHz and the value of DIV in LEUARTn_CLKDIV is  $0x0028 \text{ (LEUARTn_CLKDIV = } 0x00000140)$ . The baud rate = 22.5 kHz / (1 + 0x140 / 256) = 22.5 kHz / 2.25 = 10 kHz.

For a desired baud rate br_{DESIRED}, LEUARTn_CLKDIV can be calculated by using:

LEUARTn_CLKDIV = 256 x (fLEUARTn/br_{DESIRED} - 1)

#### Figure 19.4. LEUART CLKDIV Equation

It's important to note that this equation results in a 32bit value for the LEUARTn_CLKDIV register but only bits [16:3] are valid and all others must be 0. For example if we have a 32 kHz clock and whish to achieve a baud rate of 10 kHz the equation above results in a LEUARTn_CLKDIV value of 0x233. However, the actual value of the register will be 0x230 since bits [2:0] cannot be set. This limits the best achievable acuracy. In this example the actual baud rate will be 32 kHz / (1+ 0x230 / 255) = 10.039 kHz instead of 32 kHz / (1+ 0x233 / 255) = 10.002 kHz.

Table 19.2 LEUART Baud Rates on page 642 lists a set of desired baud rates and the closest baud rates reachable by the LEUART with a 32.768 kHz clock source. It also shows the average baud rate error.

Desired baud rate	LEUARTn_CLKDIV	LEUARTn_CLKDIV/256	Actual Baud Rate	Error [%]
300	27704	108.21875	300.0217	0.01
600	13728	53.625	599.8719	-0.02
1200	6736	26.3125	1199.744	-0.02
2400	3240	12.65625	2399.487	-0.02
4800	1488	5.8125	4809.982	0.21
9600	616	2.40625	9619.963	0.21

Table 19.2. LEUART Baud Rates

# 19.3.4 Data Transmission

Data transmission is initiated by writing data to the transmit buffer using one of the methods described in 19.3.4.1 Transmit Buffer Operation. When the transmit shift register is empty and ready for new data, a frame from the transmit buffer is loaded into the shift register, and if the transmitter is enabled, transmission begins. When the frame has been transmitted, a new frame is loaded into the shift register if available, and transmission continues. If the transmit buffer is empty, the transmitter goes to an idle state, waiting for a new frame to become available. Transmission is enabled through the command register LEUARTn_CMD by setting TXEN, and disabled by setting TXDIS. When the transmitter is disabled using TXDIS, any ongoing transmission is aborted, and any frame currently being transmitted is discarded. When disabled, the TX output goes to an idle state, which by default is a high value. Whether or not the transmitter is enabled at a given time can be read from TXENS in LEUARTn_STATUS. After a transmission, when there is no more data in the shift register or transmit buffer, the TXC flag in LEUARTn_STATUS and the TXC interrupt flag in LEUARTn_IF are set, signaling that the transmitter is idle. The TXC status flag is cleared when a new byte becomes available for transmission, but the TXC interrupt flag must be cleared by software.

# 19.3.4.1 Transmit Buffer Operation

A frame can be loaded into the transmit buffer by writing to LEUARTn_TXDATA or LEUARTn_TXDATAX. Using LEUARTn_TXDATA allows 8 bits to be written to the buffer. If 9 bit frames are used, the 9th bit will in that case be set to the value of BIT8DV in LEUARTn_CTRL. To set the 9th bit directly and/or use transmission control, LEUARTn_TXDATAX must be used. When writing data to the transmit buffer using LEUARTn_TXDATAX, the 9th bit written to LEUARTn_TXDATAX overrides the value in BIT8DV, and alone defines the 9th bit that is transmitted if 9-bit frames are used.

If a write is attempted to the transmit buffer when it is not empty, the TXOF interrupt flag in LEUARTn_IF is set, indicating the overflow. The data already in the buffer is in that case preserved, and no data is written.

In addition to the interrupt flag TXC in LEUARTn_IF and the status flag TXC in LEUARTn_STATUS which are set when the transmitter becomes idle, TXBL in LEUARTn_STATUS and the TXBL interrupt flag in LEUARTn_IF are used to indicate the level of the transmit buffer. Whenever the transmit buffer becomes empty, these flags are set high. Both the TXBL status flag and the TXBL interrupt flag are cleared automatically when data is written to the transmit buffer.

There is also TXIDLE status in LEUART_STATUS which can be used to detect when the transmit state machine is in the idle state.

The transmit buffer, including the TX shift register can be cleared by setting command bit CLEARTX in LEUARTn_CMD. This will prevent the LEUART from transmitting the data in the buffer and shift register, and will make them available for new data. Any frame currently being transmitted will not be aborted. Transmission of this frame will be completed. An overview of the operation of the transmitter is shown in Figure 19.5 LEUART Transmitter Overview on page 643.

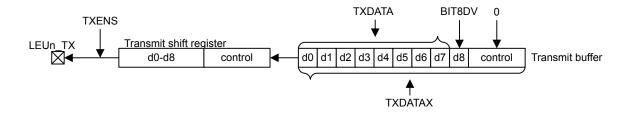

Figure 19.5. LEUART Transmitter Overview

#### 19.3.4.2 Frame Transmission Control

The transmission control bits, which can be written using LEUARTn_TXDATAX, affect the transmission of the written frame. The following options are available:

- Generate break: By setting TXBREAK, the output will be held low during the first stop-bit period to generate a framing error. A receiver that supports break detection detects this state, allowing it to be used e.g. for framing of larger data packets. The line is driven high for one bit period before the next frame is transmitted so the next start condition can be identified correctly by the recipient. Continuous breaks lasting longer than an UART frame are thus not supported by the LEUART. GPIO can be used for this. Note that when AUTOTRI in LEUARTn_CTRL is used, the transmitter is not tristated before the high-bit after the break has been transmitted.
- · Disable transmitter after transmission: If TXDISAT is set, the transmitter is disabled after the frame has been fully transmitted.
- Enable receiver after transmission: If RXENAT is set, the receiver is enabled after the frame has been fully transmitted. It is enabled in time to detect a start-bit directly after the last stop-bit has been transmitted.

The transmission control bits in the LEUART cannot tristate the transmitter. This is performed automatically by hardware if AUTOTRI in LEUARTn_CTRL is set. See 19.3.7 Half Duplex Communication for more information on half duplex operation.

# 19.3.5 Data Reception

Data reception is enabled by setting RXEN in LEUARTn_CMD. When the receiver is enabled, it actively samples the input looking for a transition from high to low indicating the start bit of a new frame. When a start bit is found, reception of the new frame begins if the receive shift register is empty and ready for new data. When the frame has been received, it is pushed into the receive buffer, making the shift register ready for another frame of data, and the receiver starts looking for another start bit. If the receive buffer is full, the received frame remains in the shift register until more space in the receive buffer is available.

If an incoming frame is detected while both the receive buffer and the receive shift register are full, the data in the receive shift register is overwritten, and the RXOF interrupt flag in LEUARTn_IF is set to indicate the buffer overflow.

The receiver can be disabled by setting the command bit RXDIS in LEUARTn_CMD. Any frame currently being received when the receiver is disabled is discarded. Whether or not the receiver is enabled at a given time can be read out from RXENS in LEUARTn_STATUS.

The receive buffer,can be cleared by setting command bit CLEARRX in LEUARTn_CMD. This will make it avaliable for new data. Any frame currently being received will not be aborted and will become the first received frame when complete.

# 19.3.5.1 Receive Buffer Operation

When data becomes available in the receive buffer, the RXDATAV flag in LEUARTn_STATUS and the RXDATAV interrupt flag in LEUARTn_IF are set. Both the RXDATAV status flag and the RXDATAV interrupt flag are cleared by hardware when data is no longer available, i.e. when data has been read out of the buffer.

Data can be read from receive buffer using either LEUARTn_RXDATA or LEUARTn_RXDATAX. LEUARTn_RXDATA gives access to the 8 least significant bits of the received frame, while LEUARTn_RXDATAX must be used to get access to the 9th, most significant bit. The LEUARTn_RXDATAX register also contains status information regarding the frame.

When a frame is read from the receive buffer using LEUARTn_RXDATA or LEUARTn_RXDATAX, the frame is removed from the buffer, making room for a new one. If an attempt is done to read more frames from the buffer than what is available, the RXUF interrupt flag in LEUARTn IF is set to signal the underflow, and the data read from the buffer is undefined.

Frames can also be read from the receive buffer without removing the data by using LEUARTn_RXDATAXP, which gives access to the frame in the buffer including control bits. Data read from this register when the receive buffer is empty is undefined. No underflow interrupt is generated by a read using LEUARTn_RXDATAXP, i.e. the RXUF interrupt flag is never set as a result of reading from LEUARTn_RXDATAXP.

An overview of the operation of the receiver is shown in Figure 19.6 LEUART Receiver Overview on page 644.

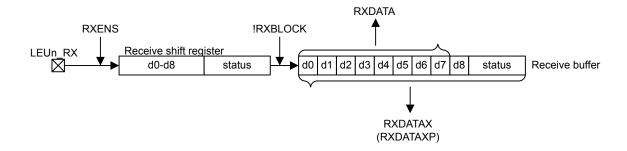

Figure 19.6. LEUART Receiver Overview

# 19.3.5.2 Blocking Incoming Data

When using hardware frame recognition, as detailed in 19.3.5.6 Programmable Start Frame, 19.3.5.7 Programmable Signal Frame, and 19.3.5.8 Multi-Processor Mode, it is necessary to be able to let the receiver sample incoming frames without passing the frames to software by loading them into the receive buffer. This is accomplished by blocking incoming data.

Incoming data is blocked as long as RXBLOCK in LEUARTn_STATUS is set. When blocked, frames received by the receiver will not be loaded into the receive buffer, and software is not notified by the RXDATAV bit in LEUARTn_STATUS or the RXDATAV interrupt flag in LEUARTn_IF at their arrival. For data to be loaded into the receive buffer, RXBLOCK must be cleared in the instant a frame is fully received by the receiver. RXBLOCK is set by setting RXBLOCKEN in LEUARTn_CMD and disabled by setting RXBLOCKDIS also in LEUARTn_CMD. There are two exceptions where data is loaded into the receive buffer even when RXBLOCK is set. The first is when an address frame is received when in operating in multi-processor mode as shown in 19.3.5.8 Multi-Processor Mode. The other case is when receiving a start-frame when SFUBRX in LEUARTn_CTRL is set; see 19.3.5.6 Programmable Start Frame

Frames received containing framing or parity errors will not result in the FERR and PERR interrupt flags in LEUARTn_IF being set while RXBLOCK is set. Hardware recognition is not applied to these erroneous frames, and they are silently discarded.

### Note:

- If a frame is received while RXBLOCK in LEUARTn_STATUS is cleared, but stays in the receive shift register because the receive buffer is full, the received frame will be loaded into the receive buffer when space becomes available even if RXBLOCK is set at that time
- The overflow interrupt flag RXOF in LEUARTn_IF will be set if a frame in the receive shift register, waiting to be loaded into the receive buffer is overwritten by an incoming frame even though RXBLOCK is set.

### 19.3.5.3 Data Sampling

The receiver samples each incoming bit as close as possible to the middle of the bit-period. Except for the start-bit, only a single sample is taken of each of the incoming bits.

The length of a bit-period is given by 1 + LEUARTn_CLKDIV/256, as a number of 32.768 kHz clock periods. Let the clock cycle where a start-bit is first detected be given the index 0. The optimal sampling point for each bit in the UART frame is then given by the following equation:

 $S_{opt}(n) = n (1 + LEUARTn_CLKDIV/256) + LEUARTn_CLKDIV/512$ 

Figure 19.7. LEUART Optimal Sampling Point

where n is the bit-index.

Since samples are only done on the positive edges of the 32.768 kHz clock, the actual samples are performed on the closest positive edge, i.e. the edge given by the following equation:

 $S(n) = floor(n \times (1 + LEUARTn CLKDIV/256) + LEUARTn CLKDIV/512)$ 

# Figure 19.8. LEUART Actual Sampling Point

The sampling location will thus have jitter according to difference between  $S_{opt}$  and S. The start-bit is found at n=0, then follows the data bits, any parity bit, and the stop bits.

If the value of the start-bit is found to be high, then the start-bit is discarded, and the receiver waits for a new start-bit.

## 19.3.5.4 Parity Error

When the parity bit is enabled, a parity check is automatically performed on incoming frames. When a parity error is detected in a frame, the data parity error bit PERR in the frame is set, as well as the interrupt flag PERR. Frames with parity errors are loaded into the receive buffer like regular frames.

PERR can be accessed by reading the frame from the receive buffer using the LEUARTn_RXDATAX register.

# 19.3.5.5 Framing Error and Break Detection

A framing error is the result of a received frame where the stop bit was sampled to a value of 0. This can be the result of noise and baud rate errors, but can also be the result of a break generated by the transmitter on purpose.

When a framing error is detected, the framing error bit FERR in the received frame is set. The interrupt flag FERR in LEUARTn_IF is also set. Frames with framing errors are loaded into the receive buffer like regular frames.

FERR can be accessed by reading the frame from the receive buffer using the LEUARTn_RXDATAX or LEUARTn_RXDATAXP registers.

#### 19.3.5.6 Programmable Start Frame

The LEUART can be configured to start receiving data when a special start frame is detected on the input. This can be useful when operating in low energy modes, allowing other devices to gain the attention of the LEUART by transmitting a given frame.

When SFUBRX in LEUARTn_CTRL is set, an incoming frame matching the frame defined in LEUARTn_STARTFRAME will result in RXBLOCK in LEUARTn_STATUS being cleared. This can be used to enable reception when a specified start frame is detected. If the receiver is enabled and blocked, i.e. RXENS and RXBLOCK in LEUARTn_STATUS are set, the receiver will receive all incoming frames, but unless an incoming frame is a start frame it will be discarded and not loaded into the receive buffer. When a start frame is detected, the block is cleared, and frames received from that point, including the start frame, are loaded into the receive buffer.

An incoming start frame results in the STARTF interrupt flag in LEUARTn_IF being set, regardless of the value of SFUBRX in LEUARTn CTRL. This allows an interrupt to be made when the start frame is detected.

When 8 data-bit frame formats are used, only the 8 least significant bits of LEUARTn_STARTFRAME are compared to incoming frames. The full length of LEUARTn_STARTFRAME is used when operating with frames consisting of 9 data bits.

**Note:** The receiver must be enabled for start frames to be detected. In addition, a start frame with a parity error or framing error is not detected as a start frame.

#### 19.3.5.7 Programmable Signal Frame

As well as the configurable start frame, a special signal frame can be specified. When a frame matching the frame defined in LEUARTn_SIGFRAME is detected by the receiver, the SIGF interrupt flag in LEUARTn_IF is set. As for start frame detection, the receiver must be enabled for signal frames to be detected.

One use of the programmable signal frame is to signal the end of a multi-frame message transmitted to the LEUART. An interrupt will then be triggered when the packet has been completely received, allowing software to process it. Used in conjunction with the programmable start frame and DMA, this makes it possible for the LEUART to automatically begin the reception of a packet on a specified start frame, load the entire packet into memory, and give an interrupt when reception of a packet has completed. The device can thus wait for data packets in EM2 Deep Sleep, and only be woken up when a packet has been completely received.

A signal frame with a parity error or framing error is not detected as a signal frame.

#### 19.3.5.8 Multi-Processor Mode

To simplify communication between multiple processors and maintain compatibility with the USART, the LEUART supports a multi-processor mode. In this mode the 9th data bit in each frame is used to indicate whether the content of the remaining 8 bits is data or an address.

When multi-processor mode is enabled, an incoming 9-bit frame with the 9th bit equal to the value of MPAB in LEUARTn_CTRL is identified as an address frame. When an address frame is detected, the MPAF interrupt flag in LEUARTn_IF is set, and the address frame is loaded into the receive register. This happens regardless of the value of RXBLOCK in LEUARTn_STATUS.

Multi-processor mode is enabled by setting MPM in LEUARTn_CTRL. The mode can be used in buses with multiple slaves, allowing the slaves to be addressed using the special address frames. An addressed slave, which was previously blocking reception using RXBLOCK, would then unblock reception, receive a message from the bus master, and then block reception again, waiting for the next message. See the USART for a more detailed example.

**Note:** The programmable start frame functionality can be used for automatic address matching, enabling reception on a correctly configured incoming frame.

An address frame with a parity error or a framing error is not detected as an address frame. The Start, Signal, and address frames should not be set to match the same frame since each of these uses separate synchronization to the peripherial clock domain.

## 19.3.6 Loopback

The LEUART receiver samples LEUn_RX by default, and the transmitter drives LEUn_TX by default. This is not the only configuration however. When LOOPBK in LEUARTn_CTRL is set, the receiver is connected to the LEUn_TX pin as shown in Figure 19.9 LEUART Local Loopback on page 647. This is useful for debugging, as the LEUART can receive the data it transmits, but it is also used to allow the LEUART to read and write to the same pin, which is required for some half duplex communication modes. In this mode, the LEUn_TX pin must be enabled as an output in the GPIO.

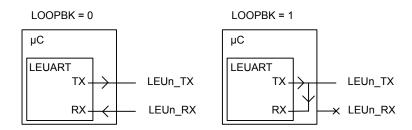

Figure 19.9. LEUART Local Loopback

#### 19.3.7 Half Duplex Communication

When doing full duplex communication, two data links are provided, making it possible for data to be sent and received at the same time. In half duplex mode, data is only sent in one direction at a time. There are several possible half duplex setups, as described in the following sections.

# 19.3.7.1 Single Data-link

In this setup, the LEUART both receives and transmits data on the same pin. This is enabled by setting LOOPBK in LEUARTn_CTRL, which connects the receiver to the transmitter output. Because they are both connected to the same line, it is important that the LEUART transmitter does not drive the line when receiving data, as this would corrupt the data on the line.

When communicating over a single data-link, the transmitter must thus be tristated whenever not transmitting data. If AUTOTRI in LEUARTn_CTRL is set, the LEUART automatically tristates LEUn_TX whenever the transmitter is inactive. It is then the responsibility of the software protocol to make sure the transmitter is not transmitting data whenever incoming data is expected.

The transmitter can also be tristated from software by configuring the GPIO pin as an input and disabling the LEUART output on LEUn_TX.

**Note:** Another way to tristate the transmitter is to enable wired-and or wired-or mode in GPIO. For wired-and mode, outputting a 1 will be the same as tristating the output, and for wired-or mode, outputting a 0 will be the same as tristating the output. This can only be done on buses with a pull-up or pull-down resistor respectively.

#### 19.3.7.2 Single Data-link With External Driver

Some communication schemes, such as RS-485 rely on an external driver. Here, the driver has an extra input which enables it, and instead of Tristating the transmitter when receiving data, the external driver must be disabled. The USART has hardware support for automatically turning the driver on and off. When using the LEUART in such a setup, the driver must be controlled by a GPIO. Figure 19.10 LEUART Half Duplex Communication with External Driver on page 648 shows an example configuration using an external driver.

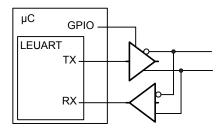

Figure 19.10. LEUART Half Duplex Communication with External Driver

# 19.3.7.3 Two Data-links

Some limited devices only support half duplex communication even though two data links are available. In this case software is responsible for making sure data is not transmitted when incoming data is expected.

## 19.3.8 Transmission Delay

By configuring TXDELAY in LEUARTn_CTRL, the transmitter can be forced to wait a number of bit-periods from when it is ready to transmit data, to when it actually transmits the data. This delay is only applied to the first frame transmitted after the transmitter has been idle. When transmitting frames back-to-back the delay is not introduced between the transmitted frames.

This is useful on half duplex buses, because the receiver always returns received frames to software during the first stop-bit. The bus may still be driven for up to 3 bit periods, depending on the current frame format. Using the transmission delay, a transmission can be started when a frame is received, and it is possible to make sure that the transmitter does not begin driving the output before the frame on the bus is completely transmitted.

To route the UART TX and RX signals to a pin first select the desired pins using the RXLOC and TXLOC fields in the LEUARTn_ROUTELOC0 register. Then enable the connection using TXPEN and RXPEN in the LEUARTn_ROUTPEN register. See the device data sheet for mappings between UART locations (LOC0, LOC1, etc.) and device pins (PA0, PA1, etc.).

#### **19.3.9 PRS RX Input**

In addition to receiving data on an external pin the LEUART can be configured to receive data directly from a PRS channel by setting RX_PRS in LEUARTn_INPUT. The PRS channel used can be selected using RX_PRS_SEL in LEUARTn_INPUT. See the PRS chapter for more details on the PRS block.

For example the output of a comparator could be routed to the LEUART through the PRS to allow for receiving a signal with low peak-to-peak voltage or a significant DC offset.

#### 19.3.10 DMA Support

The LEUART has full DMA support in energy modes EM0 Active – EM2 Deep Sleep. The DMA controller can write to the transmit buffer using the registers LEUARTn_TXDATA and LEUARTn_TXDATAX, and it can read from receive buffer using the registers LEUARTn_RXDATA and LEUARTn_RXDATAX. This enables single byte transfers and 9 bit data + control/status bits transfers both to and from the LEUART. The DMA will start up the HFRCO and run from this when it is waken by the LEUART in EM2. The HFRCO is disabled once the transaction is done.

A request for the DMA controller to read from the receive buffer can come from one of the following sources:

· Receive buffer full

A write request can come from one of the following sources:

- · Transmit buffer and shift register empty. No data to send.
- · Transmit buffer empty

In some cases, it may be sensible to temporarily stop DMA access to the LEUART when a parity or framing error has occurred. This is enabled by setting ERRSDMA in LEUARTn_CTRL. When this bit is set, the DMA controller will not get requests from the receive buffer if a framing error or parity error is detected in the received byte. The ERRSDMA bit applies only to the RX DMA.

When operating in EM2 Deep Sleep, the DMA controller must be powered up in order to perform the transfer. This is automatically performed for read operations if RXDMAWU in LEUARTn_CTRL is set and for write operations if TXDMAWU in LEUARTn_CTRL is set. To make sure the DMA controller still transfers bits to and from the LEUART in low energy modes, these bits must thus be configured accordingly.

**Note:** When RXDMAWU or TXDMAWU is set, the system will not be able to go to EM2 Deep Sleep/EM3 Stop before all related LEUART DMA requests have been processed. This means that if RXDMAWU is set and the LEUART receives a frame, the system will not be able to go to EM2 Deep Sleep/EM3 Stop before the frame has been read from the LEUART. In order for the system to go to EM2 during the last byte transmission, LEUART_CTRL_TXDMAWU must be cleared in the DMA interrupt service routine. This is because TXBL will be high during that last byte transfer.

#### 19.3.11 Pulse Generator/ Pulse Extender

The LEUART has an optional pulse generator for the transmitter output, and a pulse extender on the receiver input. These are enabled by setting PULSEEN in LEUARTn_PULSECTRL, and with INV in LEUARTn_CTRL set, they will change the output/input format of the LEUART from NRZ to RZI as shown in Figure 19.11 LEUART - NRZ vs. RZI on page 649.

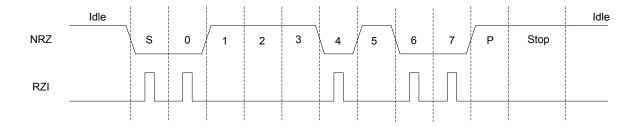

Figure 19.11. LEUART - NRZ vs. RZI

If PULSEEN in LEUARTn_PULSECTRL is set while INV in LEUARTn_CTRL is cleared, the output waveform will look like RZI shown in Figure 19.11 LEUART - NRZ vs. RZI on page 649, only inverted.

The width of the pulses from the pulse generator can be configured using PULSEW in LEUARTn_PULSECTRL. The generated pulse width is PULSEW + 1 cycles of the 32.768 kHz clock, which makes pulse width from 31.25µs to 500µs possible.

Since the incoming signal is only sampled on positive clock edges, the width of the incoming pulses must be at least two 32.768 kHz clock periods wide for reliable detection by the LEUART receiver. They must also be shorter than half a UART bit period.

At 2400 baud or lower, the pulse generator is able to generate RZI pulses compatible with the IrDA physical layer specification. The external IrDA device must generate pulses of sufficient length for successful two-way communication.

PULSEFILT in the LEUARTn_PULSECTRL register can be used to extend the minimum receive pulse width from 2 clock periods to 3 clock periods.

### 19.3.11.1 Interrupts

The interrupts generated by the LEUART are combined into one interrupt vector. If LEUART interrupts are enabled, an interrupt will be made if one or more of the interrupt flags in LEUARTn_IF and their corresponding bits in LEUART_IEN are set.

### 19.3.12 Register Access

Since this module is a Low Energy Peripheral, and runs off a clock which is asynchronous to the HFCORECLK, special considerations must be taken when accessing registers. Refer to 4.3 Access to Low Energy Peripherals (Asynchronous Registers) for a description on how to perform register accesses to Low Energy Peripherals.

The registers LEUARTn_FREEZE and LEUARTn_SYNCBUSY are used for synchronization of this peripheral.

### 19.4 Register Map

The offset register address is relative to the registers base address.

B.//	N.			
Bit	Name	Reset	Access	Description
10	MPAB	0	RW	Multi-Processor Address-Bit
		e of the multi-proc nulti-processor add		s bit. An incoming frame with its 9th bit equal to the value of this bit marks
9	MPM	0	RW	Multi-Processor Mode
	Set to enable mu	ılti-processor mod	e.	
	Value			Description
	0			The 9th bit of incoming frames have no special function
	1			An incoming frame with the 9th bit equal to MPAB will be loaded into the receive buffer regardless of RXBLOCK and will result in the MPAB interrupt flag being set
8	SFUBRX	0	RW	Start-Frame UnBlock RX
	Clears RXBLOC	K when the start-f	rame is found	in the incoming data. The start-frame is loaded into the receive buffer.
	Value			Description
	0			Detected start-frames have no effect on RXBLOCK
	1			When a start-frame is detected, RXBLOCK is cleared and the start-frame is loaded into the receive buffer
7	LOOPBK	0	RW	Loopback Enable
	Set to connect re	eceiver to LEUn_T	X instead of L	EUn_RX.
	Value			Description
	0			The receiver is connected to and receives data from LEUn_RX
	1			The receiver is connected to and receives data from LEUn_TX
6	ERRSDMA	0	RW	Clear RX DMA on Error
	When set, RX D	MA requests will b	e cleared on t	framing and parity errors.
	Value			Description
	0			Framing and parity errors have no effect on DMA requests from the LEUART
	1			RX DMA requests from the LEUART are disabled if a framing error or parity error occurs.
5	INV	0	RW	Invert Input and Output
	Set to invert the	output on LEUn_T	X and input o	n LEUn_RX.
	Value			Description
	0			A high value on the input/output is 1, and a low value is 0.
	1			A low value on the input/output is 1, and a high value is 0.
4	STOPBITS	0	RW	Stop-Bit Mode
	Determines the r present.	number of stop-bit	s used. Only ι	used when transmitting data. The receiver only verifies that one stop bit is
	Value	Mode		Description
		-		<u> </u>

Bit	Name	Reset	Access	Description
	0	ONE		One stop-bit is transmitted with every frame
	1	TWO		Two stop-bits are transmitted with every frame
3:2	PARITY	0x0	RW	Parity-Bit Mode
	Determines wheth	her parity bits are e	enabled, and	I whether even or odd parity should be used.
	Value	Mode		Description
	0	NONE		Parity bits are not used
	2	EVEN		Even parity are used. Parity bits are automatically generated and checked by hardware.
	3	ODD		Odd parity is used. Parity bits are automatically generated and checked by hardware.
1	DATABITS	0	RW	Data-Bit Mode
	This register sets	the number of data	a bits.	
	Value	Mode		Description
	0	EIGHT		Each frame contains 8 data bits
	1	NINE		Each frame contains 9 data bits
0	AUTOTRI	0	RW	Automatic Transmitter Tristate
	When set, LEUn_	_TX is tristated whe	never the tr	ansmitter is inactive.
	Value			Description
	0			LEUn_TX is held high when the transmitter is inactive. INV inverts the inactive state.
	1			LEUn_TX is tristated when the transmitter is inactive

#### 20. TIMER/WTIMER - Timer/Counter

#### **Quick Facts**

#### What?

The TIMER (Timer/Counter) keeps track of timing and counts events, generates output waveforms, and triggers timed actions in other peripherals.

#### Why?

Most applications have activities that need to be timed accurately with as little CPU intervention and energy consumption as possible.

#### How?

The flexible 16/32-bit timer can be configured to provide PWM waveforms with optional dead-time insertion (e.g. motor control) or work as a frequency generator. The timer can also count events and control other peripherals through the PRS, which offloads the CPU and reduces energy consumption.

#### 20.1 Introduction

The general purpose timer has 3 or 4 compare/capture channels for input capture and compare/Pulse-Width Modulation (PWM) output.

The TIMER and WTIMER peripherals are identical except for the timer width. A TIMER is 16-bits wide and a WTIMER is 32-bits wide. Some timers also include a Dead-Time Insertion module suitable for motor control applications.

Refer to the device data sheet to determine the capabilities (capture/compare channel count and DTI) of each timer instance.

#### 20.2 Features

- · 16/32-bit auto reload up/down counter
  - Dedicated 16/32-bit reload register which serves as counter maximum
- 3 or 4 Compare/Capture channels
  - · Individually configurable as either input capture or output compare/PWM
- · Multiple Counter modes
  - · Count up
  - · Count down
  - · Count up/down
  - · Quadrature Decoder
  - · Direction and count from external pins
- · 2x Count Mode
- · Counter control from PRS or external pin
  - Start
  - Stop
  - · Reload and start
- · Inter-Timer connection
- · Allows 32-bit counter mode
  - · Start/stop synchronization between several timers
- · Input Capture
  - · Period measurement
  - · Pulse width measurement
  - · Two capture registers for each capture channel
    - · Capture on either positive or negative edge
    - · Capture on both edges
  - · Optional digital noise filtering on capture inputs
- · Output Compare
  - · Compare output toggle/pulse on compare match
  - · Immediate update of compare registers
- PWM
  - · Up-count PWM
  - Up/down-count PWM
  - Predictable initial PWM output state (configured by SW)
  - · Buffered compare register to ensure glitch-free update of compare values
- Clock sources
  - HFPERCLK_{TIMERn}
    - · 10-bit Prescaler
  - · External pin
  - · Peripheral Reflex System
- · Debug mode
  - · Configurable to either run or stop when processor is stopped (halt/breakpoint)
- Interrupts, PRS output and/or DMA request on:
  - · Underflow
  - · Overflow
  - · Compare/Capture event

- · Dead-Time Insertion Unit
  - · Complementary PWM outputs with programmable dead-time
    - · Dead-time is specified independently for rising and falling edge
      - · 10-bit prescaler
      - · 6-bit time value
    - · Outputs have configurable polarity
    - · Outputs can be set inactive individually by software.
  - · Configurable action on fault
    - · Set outputs inactive
    - · Clear output
    - · Tristate output
  - · Individual fault sources
    - · One or two PRS signals
    - Debugger
      - · Support for automatic restart
    - · Core lockup
  - · Configuration lock

#### 20.3 Functional Description

An overview of the TIMER/WTIMER module is shown in Figure 20.1 TIMER/WTIMER Block Overview on page 675 and it consists of a 16/32 bit up/down counter with 3 Compare/Capture channels connected to pins TIMn_CC0, TIMn_CC1, and TIMn_CC2.

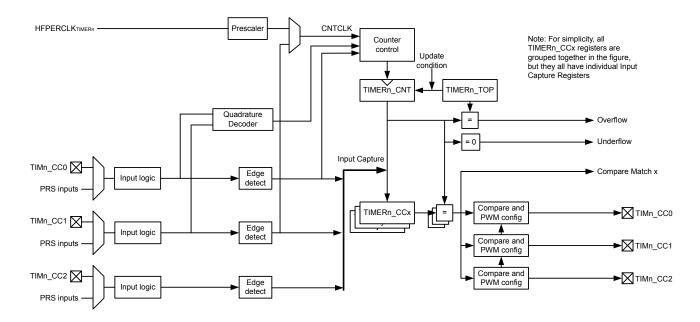

Figure 20.1. TIMER/WTIMER Block Overview

WTIMERs (Wide TIMERs) are 32-bit variants of the TIMER/WTIMER module.

#### 20.3.1 Counter Modes

The timer consists of a counter that can be configured to the following modes:

- 1. Up-count: Counter counts up until it reaches the value in TIMERn TOP, where it is reset to 0 before counting up again.
- 2. Down-count: The counter starts at the value in TIMERn_TOP and counts down. When it reaches 0, it is reloaded with the value in TIMERn_TOP.
- 3. Up/Down-count: The counter starts at 0 and counts up. When it reaches the value in TIMERn_TOP, it counts down until it reaches 0 and starts counting up again.
- 4. Quadrature Decoder: Two input channels where one determines the count direction, while the other pin triggers a clock event.

In addition, to the TIMER/WTIMER modes listed above, the TIMER/WTIMER also supports a 2x Count Mode. In this mode the counter increments/decrements by 2. The 2x Count Mode intended use is to generate 2x PWM frequency when the Compare/Capture channel is put in PWM mode. The 2x Count Mode can be enabled by setting the X2CNT bitfield in the TIMERn_CTRL register.

The counter value can be read or written by software at any time by accessing the CNT field in TIMERn_CNT.

#### 20.3.1.1 Events

Overflow is set when the counter value shifts from TIMERn_TOP to the next value when counting up. In up-count mode and Quadrature Decoder mode the next value is 0. In up/down-count mode, the next value is TIMERn_TOP-1.

Underflow is set when the counter value shifts from 0 to the next value when counting down. In down-count mode and Quadrature Decoder mode, the next value is TIMERn_TOP. In up/down-count mode the next value is 1.

An update event occurs on overflow in up-count mode and on underflow in down-count or up/down count mode. Additionally, an update event also occurs on overflow and underflow in Quadrature Decoder Mode. This event is used to time updates of buffered values.

### 20.3.1.2 Operation

Figure 20.2 TIMER/WTIMER Hardware Timer/Counter Control on page 677 shows the hardware Timer/Counter control. Software can start or stop the counter by setting the START or STOP bits in TIMERn_CMD. The counter value (CNT in TIMERn_CNT) can always be written by software to any 16/32-bit value.

It is also possible to control the counter through either an external pin or PRS input. This is done through the input logic for the Compare/Capture Channel 0. The Timer/Counter allows individual actions (start, stop, reload) to be taken for rising and falling input edges. This is configured in the RISEA and FALLA fields in TIMERn_CTRL. The reload value is 0 in up-count and up/down-count mode and TOP in down-count mode.

The RUNNING bit in TIMERn_STATUS indicates if the timer is running or not. If the SYNC bit in TIMERn_CTRL is set, the timer is started/stopped/reloaded (external pin or PRS) when any of the other timers are started/stopped/reloaded.

The DIR bit in TIMERn_STATUS indicates the counting direction of the timer at any given time. The counter value can be read or written by software through the CNT field in TIMERn_CNT. In Up/Down-Count mode the count direction will be set to up if the CNT value is written by software.

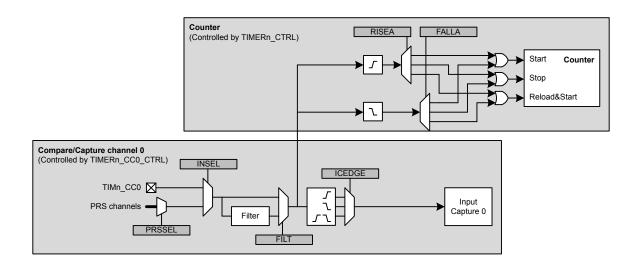

Figure 20.2. TIMER/WTIMER Hardware Timer/Counter Control

#### 20.3.1.3 Clock Source

The counter can be clocked from several sources, which are all synchronized with the peripheral clock (HFPERCLK). See Figure 20.3 TIMER/WTIMER Clock Selection on page 677.

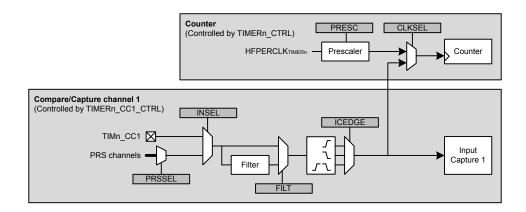

Figure 20.3. TIMER/WTIMER Clock Selection

#### 20.3.1.4 Peripheral Clock (HFPERCLK)

The peripheral clock (HFPERCLK) can be used as a source with a configurable prescale factor of 2^PRESC, where PRESC is an integer between 0 and 10, which is set in PRESC in TIMERn_CTRL. However, if 2x Count Mode is enabled and the Compare/Capture channels are put in PWM mode, the CC output is updated on both clock edges so prescaling the peripheral clock will produce an incorrect result. The prescaler is stopped and reset when the timer is stopped.

#### 20.3.1.5 Compare/ Capture Channel 1 Input

The timer can also be clocked by positive and/or negative edges on the Compare/Capture channel 1 input. This input can either come from the TIMn_CC1 pin or one of the PRS channels. The input signal must not have a higher frequency than f_{HFPERCLK}/3 when running from a pin input or a PRS input with FILT enabled in TIMERn_CCx_CTRL. When running from PRS without FILT, the frequency can be as high as f_{HFPERCLK}. Note that when clocking the timer from the same pulse that triggers a start (through RISEA/FALLA in TIMERn_CTRL), the starting pulse will not update the Counter Value.

### 20.3.1.6 Underflow/Overflow From Neighboring Timer

All timers are linked together (see Figure 20.4 TIMER/WTIMER Connections on page 678), allowing timers to count on overflow/ underflow from the lower numbered neighbouring timers to form a 32-bit or 48-bit timer. Note that all timers must be set to same count direction and less significant timer(s) can only be set to count up or down.

Figure 20.4. TIMER/WTIMER Connections

#### 20.3.1.7 One-Shot Mode

By default, the counter counts continuously until it is stopped. If the OSMEN bit is set in the TIMERn_CTRL register, however, the counter is disabled by hardware on the first *update event* (see 20.3.1.1 Events). Note that when the counter is running with CC1 as clock source (0b01 in CLKSEL in TIMERn_CTRL) and OSMEN is set, a CC1 capture event will not take place on the *update event* (CC1 rising edge) that stops the timer.

#### 20.3.1.8 Top Value Buffer

The TIMERn_TOP register can be altered either by writing it directly or by writing to the TIMER_TOPB (buffer) register. When writing to the buffer register the TIMERn_TOPB register will be written to TIMERn_TOP on the next *update event*. Buffering ensures that the TOP value is not set below the actual count value. The TOPBV flag in TIMERn_STATUS indicates whether the TIMERn_TOPB register contains data that has not yet been written to the TIMERn_TOP register (see Figure 20.5 TIMER/WTIMER TOP Value Update Functionality on page 679).

**Note:** When writing to TIMERn_TOP register directly, the TIMERn_TOPB register value will be invalidated and the TOPBV flag will be cleared. This prevents TIMERn_TOP register from being immediately updated by an existing valid TIMERn_TOPB value during the next *update event*.

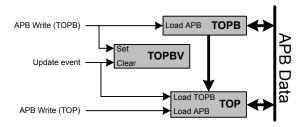

Figure 20.5. TIMER/WTIMER TOP Value Update Functionality

#### 20.3.1.9 Quadrature Decoder

Quadrature Decoding mode is used to track motion and determine both rotation direction and position. The Quadrature Decoder uses two input channels that are 90 degrees out of phase (see Figure 20.6 TIMER/WTIMER Quadrature Encoded Inputs on page 680).

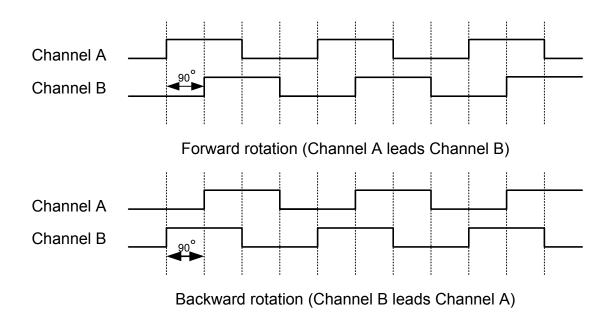

Figure 20.6. TIMER/WTIMER Quadrature Encoded Inputs

In the timer these inputs are tapped from the Compare/Capture channel 0 (Channel A) and 1 (Channel B) inputs before edge detection. The Timer/Counter then increments or decrements the counter, based on the phase relation between the two inputs. The Quadrature Decoder Mode supports two channels, but if a third channel (Z-terminal) is available, this can be connected to an external interrupt and trigger a counter reset from the interrupt service routine. By connecting a periodic signal from another timer as input capture on Compare/Capture Channel 2, it is also possible to calculate speed and acceleration.

Note: In Quadrature Decoder mode, overflow and underflow triggers an update event.

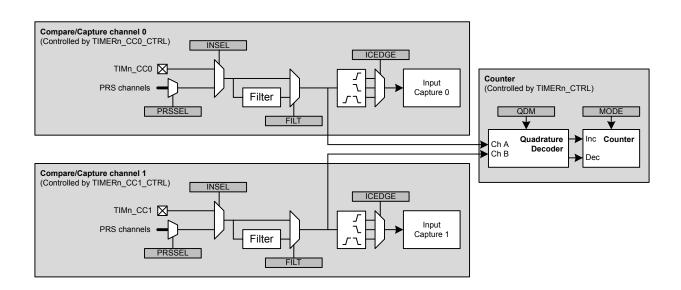

Figure 20.7. TIMER/WTIMER Quadrature Decoder Configuration

The Quadrature Decoder can be set in either X2 or X4 mode, which is configured in the QDM bit in TIMERn_CTRL. See Figure 20.7 TIMER/WTIMER Quadrature Decoder Configuration on page 680

#### 20.3.1.10 X2 Decoding Mode

In X2 Decoding mode, the counter increments or decrements on every edge of Channel A, see Table 20.1 TIMER/WTIMER Counter Response in X2 Decoding Mode on page 681 and Figure 20.8 TIMER/WTIMER X2 Decoding Mode on page 681.

Table 20.1. TIMER/WTIMER Counter Response in X2 Decoding Mode

Channel B	Channel A									
Cildililei B	Rising	Falling								
0	Increment	Decrement								
1	Decrement	Increment								

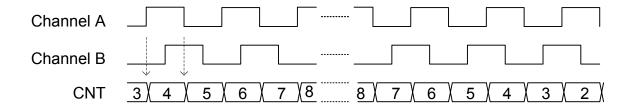

Figure 20.8. TIMER/WTIMER X2 Decoding Mode

### 20.3.1.11 X4 Decoding Mode

In X4 Decoding mode, the counter increments or decrements on every edge of Channel A and Channel B, see Figure 20.9 TIMER/WTIMER X4 Decoding Mode on page 681 and Table 20.2 TIMER/WTIMER Counter Response in X4 Decoding Mode on page 681.

Table 20.2. TIMER/WTIMER Counter Response in X4 Decoding Mode

Opposite Channel	Chan	nel A	Channel B							
	Rising	Falling	Rising	Falling						
Channel A = 0			Decrement	Increment						
Channel A = 1			Increment	Decrement						
Channel B = 0	Increment	Decrement								
Channel B = 1	Decrement	Increment								

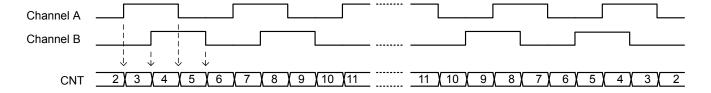

Figure 20.9. TIMER/WTIMER X4 Decoding Mode

#### 20.3.1.12 TIMER/WTIMER Rotational Position

To calculate a position Figure 20.10 TIMER/WTIMER Rotational Position Equation on page 682 can be used.

$$pos^{\circ} = (CNT/X \times N) \times 360^{\circ}$$

Figure 20.10. TIMER/WTIMER Rotational Position Equation

where X =Encoding type and N =Number of pulses per revolution.

#### 20.3.2 Compare/Capture Channels

The timer contains 3 Compare/Capture channels, which can be configured in the following modes:

- 1. Input Capture
- 2. Output Compare
- 3. PWM

### 20.3.2.1 Input Pin Logic

Each Compare/Capture channel can be configured as an input source for the Capture Unit or as external clock source for the timer (see Figure 20.11 TIMER/WTIMER Input Pin Logic on page 682). Compare/Capture channels 0 and 1 are the inputs for the Quadrature Decoder Mode. The input channel can be filtered before it is used, which requires the input to remain stable for 5 cycles in a row before the input is propagated to the output.

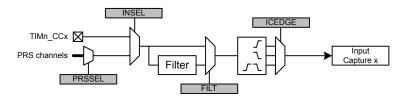

Figure 20.11. TIMER/WTIMER Input Pin Logic

### 20.3.2.2 Compare/Capture Registers

The Compare/Capture channel registers are prefixed with TIMERn_CCx_, where the x stands for the channel number. Since the Compare/Capture channels serve three functions (input capture, compare, PWM), the behavior of the Compare/Capture registers (TIMERn_CCx_CCV) and buffer registers (TIMERn_CCx_CCVB) change depending on the mode the channel is set in.

#### 20.3.2.3 Input Capture

In Input Capture Mode, the counter value (TIMERn_CNT) can be captured in the Compare/Capture Register (TIMERn_CCx_CCV) (see Figure 20.12 TIMER/WTIMER Input Capture on page 683). The CCPOL bits in TIMERn_STATUS indicate the polarity of the edge that triggered the capture in TIMERn CCx CCV.

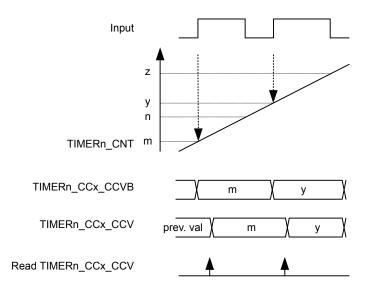

Figure 20.12. TIMER/WTIMER Input Capture

The Compare/Capture Buffer Register (TIMERn_CCx_CCVB) and the TIMERn_CCx_CCV register form double-buffered capture registers allowing two subsequent capture events to take place before a read-out is required. The first capture can always be read from TIMERn_CCx_CCV, and reading this address will load the next capture value into TIMERn_CCx_CCV from TIMERn_CCx_CCVB if it contains valid data. The CC value can be read without altering the FIFO contents by reading TIMERn_CCx_CCVP. TIMERn_CCx_CCVB can also be read without altering the FIFO contents. The ICV flag in TIMERn_STATUS indicates if there is a valid unread capture in TIMERn_CCx_CCV. In this mode, TIMERn_CCx_CCV is read-only.

In the case where a capture is triggered while both TIMERn_CCx_CCV and TIMERn_CCx_CCVB contain unread capture values, the buffer overflow interrupt flag (ICBOF in TIMERn_IF) will be set. On overflow new capture values will overwrite the value in TIMERn_CCx_CCVB and the value of TIMERn_CCx_CCV will remain unchanged. TIMERn_CCx_CCV will always contain the oldest unread value and TIMERn_CCx_CCVB will always contain the newest value.

Note: In input capture mode, the timer will only trigger interrupts when it is running.

### 20.3.2.4 Period/Pulse-Width Capture

Period and/or pulse-width capture can only be possible with Channel 0 (CC0), because this is the only channel that can start and stop the timer. This can be done by setting the RISEA field in TIMERn_CTRL to Clear&Start, and select the wanted input from either external pin or PRS, see Figure 20.13 TIMER/WTIMER Period and/or Pulse width Capture on page 684. For period capture, the Compare/Capture Channel should then be set to input capture on a rising edge of the same input signal. To capture the width of a high pulse, the Compare/Capture Channel should be set to capture on a falling edge of the input signal. To measure the low pulse-width of a signal, opposite polarities should be chosen.

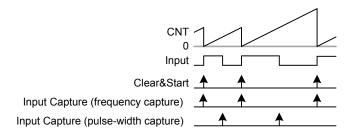

Figure 20.13. TIMER/WTIMER Period and/or Pulse width Capture

#### 20.3.2.5 Compare

Each Compare/Capture channel contains a comparator which outputs a compare match if the contents of TIMERn_CCx_CCV matches the counter value, see Figure 20.14 TIMER/WTIMER Block Diagram Showing Comparison Functionality on page 685. In compare mode, each compare channel can be configured to either set, clear or toggle the output on an event (compare match, overflow or underflow). The output from each channel is represented as an alternative function on the port it is connected to, which needs to be enabled for the CC outputs to propagate to the pins.

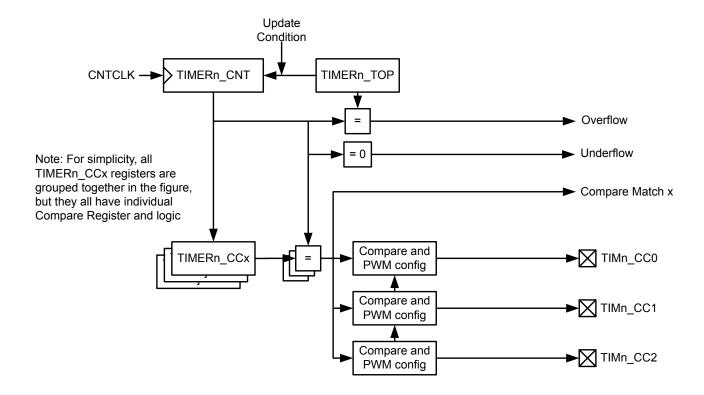

Figure 20.14. TIMER/WTIMER Block Diagram Showing Comparison Functionality

The compare output is delayed by one cycle to allow for full 0% to 100% PWM generation. If occurring in the same cycle, match action will have priority over overflow or underflow action.

The input selected (through PRSSEL, INSEL and FILTSEL in TIMERn_CCx_CTRL) for the CC channel will also be sampled on compare match and the result is found in the CCPOL bits in TIMERn_STATUS. It is also possible to configure the CCPOL to always track the inputs by setting ATI in TIMERn_CTRL.

The COIST bit in TIMERn_CCx_CTRL is the initial state of the compare/PWM output. The COIST bit can also be used as an initial value to the compare outputs on a reload-start when RSSCOIST is set in TIMERn_CTRL. Also the resulting output can be inverted by setting OUTINV in TIMERn_CCx_CTRL. It is recommended to turn off the CC channel before configuring the output state to avoid any pulses on the output. The CC channel can be turned off by setting MODE to OFF in TIMER_CCx_CTRL. The following figure shows the output logic for the TIMER/WTIMER module.

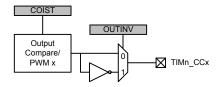

Figure 20.15. TIMER/WTIMER Output Logic

#### 20.3.2.6 Compare Mode Registers

When running in Output Compare or PWM mode, the value in TIMERn_CCx_CCV will be compared against the count value. In Compare mode the output can be configured to toggle, clear or set on compare match, overflow, and underflow through the CMOA, COFOA and CUFOA fields in TIMERn_CCx_CTRL. TIMERn_CCx_CCV can be accessed directly or through the buffer register TIMERn_CCx_CCVB, see Figure 20.16 TIMER/WTIMER Output Compare/PWM Buffer Functionality Detail on page 686. When writing to the buffer register, the value in TIMERn_CCx_CCVB will be written to TIMERn_CCx_CCV on the next *update event*. This functionality ensures glitch free PWM outputs. The CCVBV flag in TIMERn_STATUS indicates whether the TIMERn_CCx_CCVB register contains data that has not yet been written to the TIMERn_CCx_CCV register. Note that when writing 0 to TIMERn_CCx_CCVB in updown count mode the CCV value is updated when the timer counts from 0 to 1. Thus, the compare match for the next period will not happen until the timer reaches 0 again on the way down.

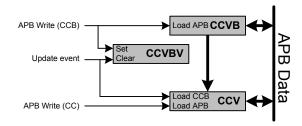

Figure 20.16. TIMER/WTIMER Output Compare/PWM Buffer Functionality Detail

### 20.3.2.7 Frequency Generation (FRG)

Frequency generation (see Figure 20.17 TIMER/WTIMER Up-count Frequency Generation on page 687) can be achieved in compare mode by:

- · Setting the counter in up-count mode
- · Enabling buffering of the TOP value.
- · Setting the CC channels overflow action to toggle

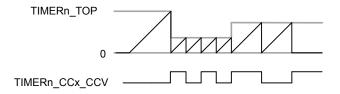

Figure 20.17. TIMER/WTIMER Up-count Frequency Generation

The output frequency is given by Figure 20.18 TIMER/WTIMER Up-count Frequency Generation Equation on page 687

$$f_{FRG} = f_{HFPERCLK}/(2^{(PRESC + 1)} \times (TOP + 1) \times 2)$$

Figure 20.18. TIMER/WTIMER Up-count Frequency Generation Equation

The figure below provides cycle accurate timing and event generation information for frequency generation.

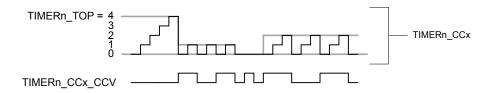

Figure 20.19. TIMER/WTIMER Up-count Frequency Generation Detail

### 20.3.2.8 Pulse-Width Modulation (PWM)

In PWM mode, TIMERn_CCx_CCV is buffered to avoid glitches in the output. The settings in the Compare Output Action configuration bits are ignored in PWM mode and PWM generation is only supported for up-count and up/down-count mode.

### 20.3.2.9 Up-count (Single-slope) PWM

If the counter is set to up-count and the Compare/Capture channel is put in PWM mode, single slope PWM output will be generated (see Figure 20.20 TIMER/WTIMER Up-count PWM Generation on page 688). In up-count mode the PWM period is TOP+1 cycles and the PWM output will be high for a number of cycles equal to TIMERn_CCx_CCV. This means that a constant high output is achieved by setting TIMERn_CCx_CCV to TOP+1 or higher. The PWM resolution (in bits) is then given by Figure 20.21 TIMER/WTIMER Up-count PWM Resolution Equation on page 688.

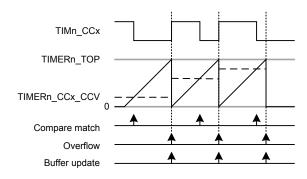

Figure 20.20. TIMER/WTIMER Up-count PWM Generation

$$R_{PWM_{UD}} = log(TOP+1)/log(2)$$

Figure 20.21. TIMER/WTIMER Up-count PWM Resolution Equation

The PWM frequency is given by Figure 20.22 TIMER/WTIMER Up-count PWM Frequency Equation on page 688:

$$f_{PWM_{UD/down}} = f_{HFPERCLK}/(2^{PRESC} \times (TOP + 1))$$

Figure 20.22. TIMER/WTIMER Up-count PWM Frequency Equation

The high duty cycle is given by Figure 20.23 TIMER/WTIMER Up-count Duty Cycle Equation on page 688

$$DS_{up} = CCVx/(TOP+1)$$

Figure 20.23. TIMER/WTIMER Up-count Duty Cycle Equation

The figure below provides cycle accurate timing and event generation information for up-count mode.

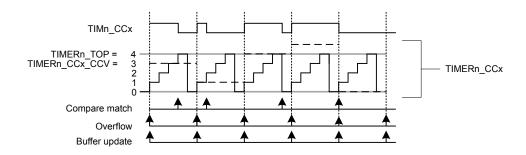

Figure 20.24. TIMER/WTIMER Up-count PWM Generation Detail

### 20.3.2.10 2x Count Mode (Up-count)

When the timer is set in 2x mode, the TIMER/WTIMER will count up by two. This will in effect make any odd Top value be rounded down to the closest even number. Similarly, any odd CC value will generate a match on the closest lower even value as shown in Figure 20.25 TIMER/WTIMER CC out in 2x mode on page 689

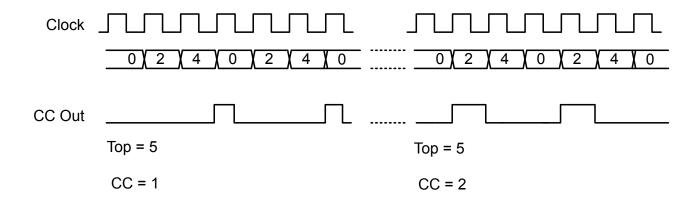

Figure 20.25. TIMER/WTIMER CC out in 2x mode

The PWM resolution is given by Figure 20.26 TIMER/WTIMER 2x PWM Resolution Equation on page 689.

 $R_{PWM_{2xmode}} = log(TOP/2+1)/log(2)$ 

Figure 20.26. TIMER/WTIMER 2x PWM Resolution Equation

The PWM frequency is given by Figure 20.27 TIMER/WTIMER 2x Mode PWM Frequency Equation (Up-count) on page 689:

 $f_{PWM_{2xmode}} = f_{HFPERCLK} / floor(TOP/2) + 1$ 

Figure 20.27. TIMER/WTIMER 2x Mode PWM Frequency Equation( Up-count)

The high duty cycle is given by Figure 20.28 TIMER/WTIMER 2x Mode Duty Cycle Equation on page 689

 $DS_{2xmode} = CCVx/((floor(TOP/2)+1)*2)$ 

Figure 20.28. TIMER/WTIMER 2x Mode Duty Cycle Equation

### 20.3.2.11 Up/Down-count (Dual-slope) PWM

If the counter is set to up-down count and the Compare/Capture channel is put in PWM mode, dual slope PWM output will be generated by Figure 20.29 TIMER/WTIMER Up/Down-count PWM Generation on page 690. The resolution (in bits) is given by Figure 20.30 TIMER/WTIMER Up/Down-count PWM Resolution Equation on page 690.

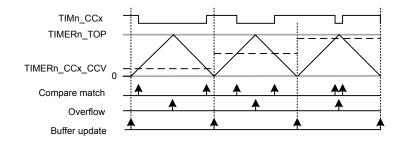

Figure 20.29. TIMER/WTIMER Up/Down-count PWM Generation

$$R_{PWM_{up/down}} = log(TOP+1)/log(2)$$

Figure 20.30. TIMER/WTIMER Up/Down-count PWM Resolution Equation

The PWM frequency is given by Figure 20.31 TIMER/WTIMER Up/Down-count PWM Frequency Equation on page 690:

$$f_{PWM_{UD/down}} = f_{HFPERCLK} / (2^{(PRESC+1)} \times TOP))$$

Figure 20.31. TIMER/WTIMER Up/Down-count PWM Frequency Equation

The high duty cycle is given by Figure 20.32 TIMER/WTIMER Up/Down-count Duty Cycle Equation on page 690

$$DS_{up/down} = CCVx/TOP$$

Figure 20.32. TIMER/WTIMER Up/Down-count Duty Cycle Equation

The figure below provides cycle accurate timing and event generation information for up-count mode.

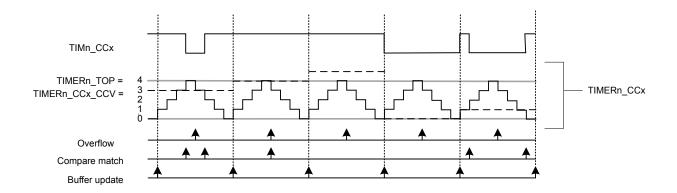

Figure 20.33. TIMER/WTIMER Up/Down-count PWM Generation

#### 20.3.2.12 2x Count Mode (Up/Down-count)

When the timer is set in 2x mode, the TIMER/WTIMER will count up/down by two. This will in effect make any odd Top value be rounded down to the closest even number. Similarly, any odd CC value will generate a match on the closest lower even value as shown in Figure 20.34 TIMER/WTIMER CC out in 2x mode on page 691

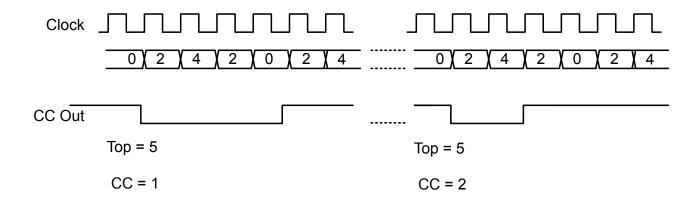

Figure 20.34. TIMER/WTIMER CC out in 2x mode

Figure 20.35 TIMER/WTIMER 2x PWM Resolution Equation on page 691.

 $R_{PWM_{2xmode}} = log(TOP/2+1)/log(2)$ 

Figure 20.35. TIMER/WTIMER 2x PWM Resolution Equation

The PWM frequency is given by Figure 20.36 TIMER/WTIMER 2x Mode PWM Frequency Equation( Up/Down-count) on page 691:

 $f_{PWM_{2ymode}} = f_{HFPERCLK} / (floor(TOP/2)*2)$ 

Figure 20.36. TIMER/WTIMER 2x Mode PWM Frequency Equation( Up/Down-count)

The high duty cycle is given by two equations based on the CCVx values. Figure 20.37 TIMER/WTIMER 2x Mode Duty Cycle Equation for CCVx = 1 or CCVx = 0 on page 691 and Figure 20.38 TIMER/WTIMER 2x Mode Duty Cycle Equation for all other CCVx = 0 odd values on page 691

 $DS_{2xmode} = (CCVx*2)/(floor(TOP/2)*4)$ 

Figure 20.37. TIMER/WTIMER 2x Mode Duty Cycle Equation for CCVx = 1 or CCVx = even

 $DS_{2xmode} = (CCVx*2 - CCVx)/(floor(TOP/2)*4)$ 

Figure 20.38. TIMER/WTIMER 2x Mode Duty Cycle Equation for all other CCVx = odd values

### 20.3.2.13 Timer Configuration Lock

To prevent software errors from making changes to the timer configuration, a configuration lock is available similar to DTI configuration Lock. Writing any value but 0xCE80 to LOCKKEY in TIMERn_LOCK results in TIMERn_CTRL, TIMERn_CMD, TIMERn_TOP, TIMERn_CNT, TIMERn_CCx_CTRL and TIMERn_CCx_CCV being locked from writing. To unlock the registers, write 0xCE80 to LOCKKEY in TIMERn_LOCK. The value of TIMERn_LOCK is 1 when the lock is active, and 0 when the registers are unlocked.

#### 20.3.3 Dead-Time Insertion Unit

Some of the timers include a Dead-Time Insertion module suitable for motor control applications. Refer to the device data sheet to check if a timer has this feature. The example settings in this section are for TIMER0, but identical settings can be used for other timers with DTI as well. The Dead-Time Insertion Unit aims to make control of brushless DC (BLDC) motors safer and more efficient by introducing complementary PWM outputs with dead-time insertion and fault handling, see Figure 20.39 TIMER/WTIMER Dead-Time Insertion Unit Overview on page 692.

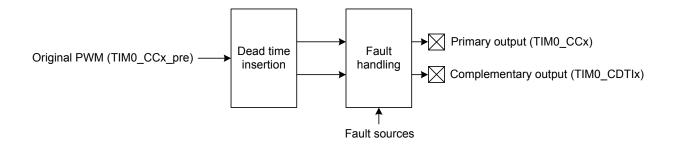

Figure 20.39. TIMER/WTIMER Dead-Time Insertion Unit Overview

When used for motor control, the PWM outputs TIM0_CC0, TIM0_CC1 and TIM0_CC2 are often connected to the high-side transistors of a triple half-bridge setup (UH, VH and WH), and the complementary outputs connected to the respective low-side transistors (UL, VL, WL shown in Figure 20.40 TIMER/WTIMER Triple Half-Bridge on page 692). Transistors used in such a bridge often do not open/close instantaneously, and using the exact complementary inputs for the high and low side of a half-bridge may result in situations where both gates are open. This can give unnecessary current-draw and short circuit the power supply. The DTI unit provides dead-time insertion to deal with this problem.

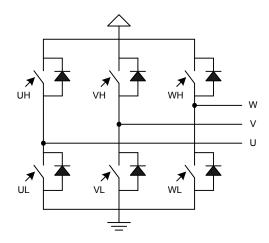

Figure 20.40. TIMER/WTIMER Triple Half-Bridge

For each of the 3 compare-match outputs of TIMER0, an additional complementary output is provided by the DTI unit. These outputs, named TIM0_CDTI0, TIM0_CDTI1 and TIM0_CDTI2 are provided to make control of e.g. 3-channel BLDC or permanent magnet AC (PMAC) motors possible using only a single timer, see Figure 20.41 TIMER/WTIMER Overview of Dead-Time Insertion Block for a Single PWM channel on page 693.

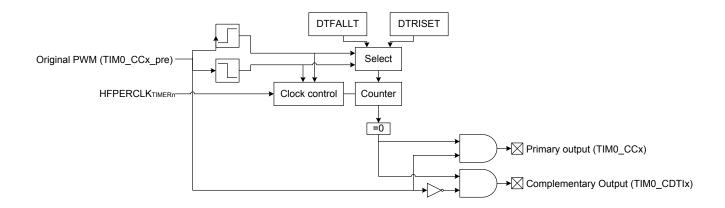

Figure 20.41. TIMER/WTIMER Overview of Dead-Time Insertion Block for a Single PWM channel

The DTI unit is enabled by setting DTEN in TIMER0_DTCTRL. In addition to providing the complementary outputs, the DTI unit then also overrides the compare match outputs from the timer.

The DTI unit gives the rising edges of the PWM outputs and the rising edges of the complementary PWM outputs a configurable time delay. By doing this, the DTI unit introduces a dead-time where both the primary and complementary outputs in a pair are inactive as seen in Figure 20.42 TIMER/WTIMER Polarity of Both Signals are Set as Active-High on page 693.

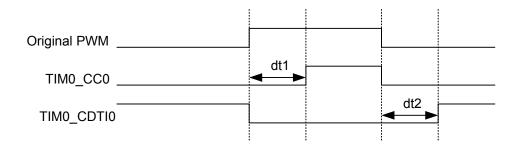

Figure 20.42. TIMER/WTIMER Polarity of Both Signals are Set as Active-High

Dead-time is specified individually for the rising and falling edge of the original PWM. These values are shared across all the three PWM channels of the DTI unit. A single prescaler value is provided for the DTI unit, meaning that both the rising and falling edge dead-times share prescaler value. The prescaler divides the HFPERCLK_{TIMERn} by a configurable factor between 1 and 1024, which is set in the DTPRESC field in TIMERO_DTTIME. The rising and falling edge dead-times are configured in DTRISET and DTFALLT in TIMERO_DTTIME to any number between 1-64 HFPERCLK_{TIMERO} cycles.

The DTAR and DTFATS bits in TIMER0_DTCTRL control the DTI output behavior when the timer stops. By default the DTI block stops when the timer is stopped. Setting the DTAR bit will cause the DTI to output on channel 0 to continue when the timer is stopped. DTAR effects only channel 0. See 20.3.3.2 PRS Channel as a Source for an example of when this can be used. While in this mode the undivided HFPERCLK_TIMER0 (DTPRESC=0) is always used regardless of programmed DTPRESC value in TIMER0_DTTIME. This means that rise and fall dead times are calculated assuming DTPRESC = 0.

When the timer stops DTI outputs are frozen by default, preserving their last state. To allow the outputs to go to a safe state as programmed in the DTFA field of TIMERO_DTFC register and set the DTFATS bitfield in the TIMERO_DTCTRL reg. Note that when DTAR is also set, DTAR has priority over DTFATS for DTI channel 0 output.

The following table shows the DTI output when the timer is halted.

Table 20.3. DTI Output When Timer Halted

DTAR	DTFATS	State
0	0	frozen
0	1	safe
1	0	running
1	1	running

#### 20.3.3.1 Output Polarity

The value of the primary and complementary outputs in a pair will never be set active at the same time by the DTI unit. The polarity of the outputs can be changed if this is required by the application. The active values of the primary and complementary outputs are set by the DTIPOL and DTCINV bits in the TIMERO_DTCTRL register. The DTIPOL bit of this register specifies the base polarity. If DTIPOL =0, then the outputs are active-high, and if DTIPOL = 1 they are active-low. The relative phase of the primary and complementary outputs is not changed by DTIPOL, as the polarity of both outputs is changed, see Figure 20.43 TIMER/WTIMER Output Polarities on page 694.

In some applications, it may be required that the primary outputs are active-high, while the complementary outputs are active-low. This can be accomplished by manipulating the DTCINV bit of the TIMERO_DTCTRL register, which inverts the polarity of the complementary outputs relative to the primary outputs. As an example, DTIPOL = 0 and DTCINV = 0 results in outputs with opposite phase and active-high states. Similarly, DTIPOL = 1 and DTCINV = 1 results in outputs with equal phase and the primary output will be active-high while the complementary will be active-low.

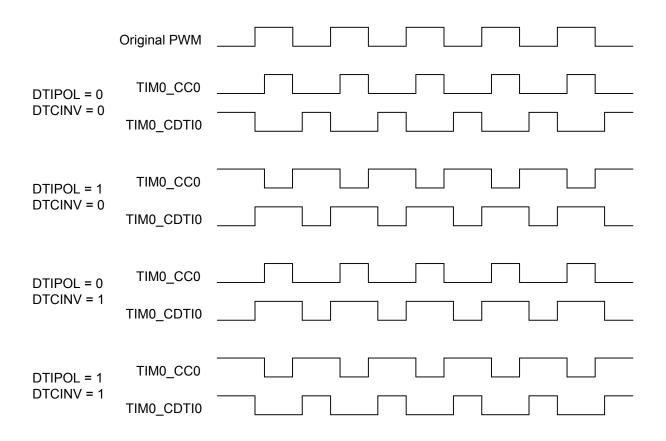

Figure 20.43. TIMER/WTIMER Output Polarities

Output generation on the individual DTI outputs can be disabled by configuring TIMER0_DTOGEN. When output generation on an output is disabled that output will go to and stay in its inactive state.

#### 20.3.3.2 PRS Channel as a Source

A PRS channel can be used as input to the DTI module instead of the PWM output from the timer for DTI channel 0. Setting DTPRSEN in TIMERO_DTCTRL will override the source of the first DTI channel, driving TIMO_CC0 and TIMO_CDTI0, with the value on the PRS channel. The rest of the DTI channels will continue to be driven by the PWM output from the timer. The input PRS channel is chosen by configuring DTPRSSEL in TIMERO_DTCTRL. Note that the timer must be running even when PRS is used as DTI source. However, if it is required to keep the DTI channel 0 running even when the timer is stopped, set DTAR in TIMERO_DTCTRL. When this bit is set, it uses DTPRESC=0 regardless of the value programmed in DTPRESC in TIMERO_DTTIME.

The DTI prescaler, set by DTPRESC in TIMER0_DTTIME determines the accuracy with which the DTI can insert dead-time into a PRS signal. The maximum dead-time error equals 2^{DTPRESC} clock cycles. With zero prescaling, the inserted dead-times are therefore accurate, but they may be inaccurate for larger prescaler settings.

#### 20.3.3.3 Fault Handling

The fault handling system of the DTI unit allows the outputs of the DTI unit to be put in a well-defined state in case of a fault. This hardware fault handling system enables a fast reaction to faults, reducing the possibility of damage to the system.

The fault sources which trigger a fault in the DTI module are determined by the bitfields of TIMER0_DTFC register. Any combination of the available error sources can be selected:

- PRS source 0, determined by DTPRS0FSEL in TIMER0_DTFC
- · PRS source 1, determined by DTPRS1FSEL in TIMER0 DTFC
- Debugger
- · Core Lockup

One or two PRS channels can be used as an error source. When PRS source 0 is selected as an error source, DTPRS0FSEL determines which PRS channel is used for this source. DTPRS1FSEL determines which PRS channel is selected as PRS source 1. Note that for Core Lockup, the LOCKUPRDIS in RMU_CTRL must be set. Otherwise this will generate a full reset of the chip.

#### 20.3.3.4 Action on Fault

When a fault occurs, the bit representing the fault source is set in TIMER0_DTFAULT register, and the outputs from the DTI unit are set to a well-defined state. The following options are available, and can be enabled by configuring DTFACT in TIMER0_DTFC:

- · Set outputs to inactive level
- · Clear outputs
- · Tristate outputs

With the first option enabled, the output state in case of a fault depends on the polarity settings for the individual outputs. An output set to be active high will be set low if a fault is detected, while an output set to be active low will be driven high.

When a fault occurs, the fault source(s) can be read out from TIMERO DTFAULT register.

Additionally a fault action can also be triggered when the timer stops if DTFATS in TIMER0_DTCTRL is set. This allows the DTI output to go to safe state programmed in DTFACT in TIMER0_DTFC when timer stops. When DTAR and DTFATS in TIMER0_DTCTRL are both set, DTI channel 0 keeps running even when the timer stops. This is useful when DTI channel 0 has an input coming from PRS.

#### 20.3.3.5 Exiting Fault State

When a fault is triggered by the PRS system, software intervention is required to re-enable the outputs of the DTI unit. This is done by manually clearing bits in TIMER0_DTFAULT register. If the fault source as determined by checking TIMER0_DEFAULT is the debugger alone, the outputs can be automatically restarted when the debugger exits. To enable automatic restart set DTDAS in TIMER0_DCTRL. When an automatic restart occurs the DTDBGF bit in TIMER0_DTFAULT will be automatically cleared by hardware. If any other bits in the TIMER0_DTFAULT register are set when the hardware clears DTDBGF the DTI module will not exit the fault state.

#### 20.3.3.6 DTI Configuration Lock

To prevent software errors from making changes to the DTI configuration, a configuration lock is available. Writing any value but 0xCE80 to LOCKKEY in TIMER0_DTLOCK results in TIMER0_DTFC, TIMER0_DTCTRL, TIMER0_DTTIME and TIMER0_ROUTE being locked from writing. To unlock the registers, write 0xCE80 to LOCKKEY in TIMER0_DTLOCK. The value of TIMER0_DTLOCK is 1 when the lock is active, and 0 when the registers are unlocked.

#### 20.3.4 Debug Mode

When the CPU is halted in debug mode, the timer can be configured to either continue to run or to be frozen. This is configured in DEBUGRUN in TIMERn CTRL.

#### 20.3.5 Interrupts, DMA and PRS Output

The timer has 3 different types of output events:

- · Counter Underflow
- · Counter Overflow
- Compare match or input capture (one per Compare/Capture channel)

Each of the events has its own interrupt flag. Also, there is one interrupt flag for each Compare/Capture channel which is set on buffer overflow in capture mode. Buffer overflow happens when a new capture pushes an old unread capture out of the TIMERn_CCx_CCV/TIMERn_CCx_CCVB register pair.

If the interrupt flags are set and the corresponding interrupt enable bits in TIMERn_IEN are set high, the timer will send out an interrupt request. Each of the events will also lead to a one HFPERCLK_{TIMERn} cycle high pulse on individual PRS outputs. Setting PRSOCNF to LEVEL in TIMERn_CCx_CTRL will make the compare match PRS output follow the compare match output, instead of outputting one HFPERCLK_{TIMERn} cycle high pulse. Interrupts are cleared by setting the corresponding bit in the TIMERn_IFC register.

Each of the events will also set a DMA request when they occur. The different DMA requests are cleared when certain acknowledge conditions are met, see Table 20.4 TIMER/WTIMER DMA Events on page 696. Events which clear the DMA requests do not clear interrupt flags. Software must still manually clear the interrupt flag if interrupts are in use.

If DMACLRACT is set in TIMERn_CTRL, the DMA request is cleared when the triggered DMA channel is active, without having to access any timer registers. This is useful in cases where a timer event is used to trigger a DMA transfer that does not target the CCV or CCVB register.

Table 20.4. TIMER/WTIMER DMA Events

Event	Acknowledge/Clear
Underflow/Overflow	Read or write to TIMERn_CNT or TIMERn_TOPB
CC 0	Read or write to TIMERn_CC0_CCV or TIMERn_CC0_CCVB
CC 1	Read or write to TIMERn_CC1_CCV or TIMERn_CC1_CCVB
CC 2	Read or write to TIMERn_CC2_CCV or TIMERn_CC2_CCVB

#### 20.3.6 GPIO Input/Output

The TIMn_CCx inputs/outputs and TIM0_CDTIx outputs are accessible as alternate functions through GPIO. Each pin connection can be enabled/disabled separately by setting the corresponding CCxPEN or CDTIxPEN bits in TIMERn_ROUTE. The LOCATION bits in the same register can be used to move all enabled pins to alternate pins. See the device data sheet for the mapping between block locations (LOC0, LOC1, etc.) and actual device pins (PA0, PA1, etc.).

## 20.4 Register Map

The offset register address is relative to the registers base address.

Offset	Name	Туре	Description

27	CCPOL3	0	R	CC3 Polarity

In Input Capture mode, this bit indicates the polarity of the edge that triggered capture in TIMERn_CC3_CCV. In Compare/PWM mode, this bit indicates the polarity of the selected input to CC channel 3. These bits are cleared when CCMODE is written to 0b00 (Off).

Value	Mode		Description
0	LOWRISE		CC3 polarity low level/rising edge
1	HIGHFALL		CC3 polarity high level/falling edge
CCPOL2	0	R	CC2 Polarity

In Input Capture mode, this bit indicates the polarity of the edge that triggered capture in TIMERn_CC2_CCV. In Compare/PWM mode, this bit indicates the polarity of the selected input to CC channel 2. These bits are cleared when CCMODE is written to 0b00 (Off).

Value	Mode	Description
0	LOWRISE	CC2 polarity low level/rising edge
1	HIGHFALL	CC2 polarity high level/falling edge
CCPOL1	0 R	CC1 Polarity

In Input Capture mode, this bit indicates the polarity of the edge that triggered capture in TIMERn_CC1_CCV. In Compare/PWM mode, this bit indicates the polarity of the selected input to CC channel 1. These bits are cleared when CCMODE is written to 0b00 (Off).

Value	Mode		Description
0	LOWRISE		CC1 polarity low level/rising edge
1	HIGHFALI	L	CC1 polarity high level/falling edge
CCPOL0	0	R	CC0 Polarity

In Input Capture mode, this bit indicates the polarity of the edge that triggered capture in TIMERn_CC0_CCV. In Compare/PWM mode, this bit indicates the polarity of the selected input to CC channel 0. These bits are cleared when CCMODE is written to 0b00 (Off).

Value	Mode	Description
0	LOWRISE	CC0 polarity low level/rising edge
1	HIGHFALL	CC0 polarity high level/falling edge

### 21. LETIMER - Low Energy Timer

#### **Quick Facts**

#### What?

The LETIMER is a down-counter that can keep track of time and output configurable waveforms. Running on a 32768 Hz clock, the LETIMER is available in EM0 Active, EM1 Sleep, EM2 Deep Sleep, and EM3 Stop.

#### Why?

The LETIMER can be used to provide repeatable waveforms to external components while remaining in EM2 Deep Sleep. It is well suited for applications such as metering systems or to provide more compare values than available in the RTC.

#### How?

With buffered repeat and top value registers, the LE-TIMER can provide glitch-free waveforms at frequencies up to 16 kHz. It can be coupled with RTC using PRS, allowing advanced time-keeping and wake-up functions in EM2 Deep Sleep and EM3 Stop

#### 21.1 Introduction

The unique LETIMERTM, the Low Energy Timer, is a 16-bit timer that is available in energy mode EM0 Active, EM1 Sleep, EM2 Deep Sleep, and EM3 Stop. Because of this, it can be used for timing and output generation when most of the device is powered down, allowing simple tasks to be performed while the power consumption of the system is kept at an absolute minimum.

The LETIMER can be used to output a variety of waveforms with minimal software intervention. It can also be connected to the Real Time Counter (RTC) using PRS, and can be configured to start counting on compare matches from the RTC.

#### 21.2 Features

- · 16-bit down count timer
- · 2 Compare match registers
- · Compare register 0 can be top timer top value
- · Compare registers can be double buffered
- · Double buffered 8-bit Repeat Register
- · Same clock source as the Real Time Counter
- · LETIMER can be triggered (started) by an RTC event via PRS or by software
- · LETIMER can be started, stopped, and/or cleared by PRS
- · 2 output pins can optionally be configured to provide different waveforms on timer underflow:
  - · Toggle output pin
  - Apply a positive pulse (pulse width of one LFACLK_{LETIMER} period)
  - PWM
- Interrupt on:
  - · Compare matches
  - Timer underflow
  - · Repeat done
- · Optionally runs during debug
- · PRS Output

#### 21.3 Functional Description

An overview of the LETIMER module is shown in Figure 21.1 LETIMER Overview on page 737. The LETIMER is a 16-bit down-counter with two compare registers, LETIMERn_COMP0 and LETIMERn_COMP1. The LETIMERn_COMP0 register can optionally act as a top value for the counter. The repeat counter LETIMERn_REP0 allows the timer to count a specified number of times before it stops. Both the LETIMERn_COMP0 and LETIMERn_REP0 registers can be double buffered by the LETIMERn_COMP1 and LETIMERn_REP1 registers to allow continuous operation. The timer can generate a single pin output, or two linked outputs.

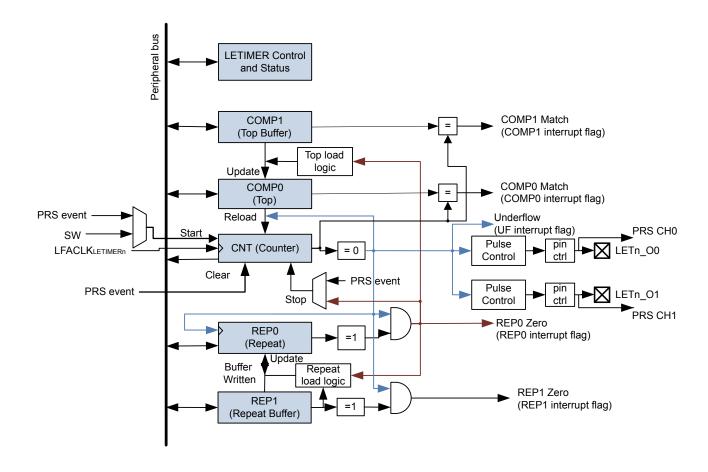

Figure 21.1. LETIMER Overview

### 21.3.1 Timer

The timer is started by setting command bit START in LETIMERn_CMD, and stopped by setting the STOP command bit in the same register. RUNNING in LETIMERn_STATUS is set as long as the timer is running. The timer can also be started on external signals, such as a compare match from the Real Time Counter. If START and STOP are set at the same time, STOP has priority, and the timer will be stopped.

The timer value can be read using the LETIMERn_CNT register. The value can be written, and it can also be cleared by setting the CLEAR command bit in LETIMERn_CMD. If the CLEAR and START commands are issued at the same time, the timer will be cleared, then start counting at the top value.

### 21.3.2 Compare Registers

The LETIMER has two compare match registers, LETIMERn_COMP0 and LETIMERn_COMP1. Each of these compare registers are capable of generating an interrupt when the counter value LETIMERn_CNT becomes equal to their value. When LETIMERn_CNT becomes equal to the value of LETIMERn_COMP0, the interrupt flag COMP0 in LETIMERn_IF is set, and when LETIMERn_CNT becomes equal to the value of LETIMERn_COMP1, the interrupt flag COMP1 in LETIMERn_IF is set.

### 21.3.3 Top Value

If COMP0TOP in LETIMERn_CTRL is set, the value of LETIMERn_COMP0 acts as the top value of the timer, and LETIMERn_COMP0 is loaded into LETIMERn_CNT on timer underflow. If COMP0TOP is cleared to 0, the timer wraps around to 0xFFFF. The underflow interrupt flag UF in LETIMERn IF is set when the timer reaches zero.

### 21.3.3.1 Buffered Top Value

If BUFTOP in LETIMERn_CTRL is set, the value of LETIMERn_COMP0 is buffered by LETIMERn_COMP1. In this mode, the value of LETIMERn_COMP1 is loaded into LETIMERn_COMP0 every time LETIMERn_REP0 is about to decrement to 0. This can for instance be used in conjunction with the buffered repeat mode to generate continually changing output waveforms.

Write operations to LETIMERn COMP0 have priority over buffer loads.

### 21.3.3.2 Repeat Modes

By default, the timer wraps around to the top value or 0xFFFF on each underflow, and continues counting. The repeat counters can be used to get more control of the operation of the timer, including defining the number of times the counter should wrap around. Four different repeat modes are available, see Table 21.1 LETIMER Repeat Modes on page 738.

**Table 21.1. LETIMER Repeat Modes** 

REPMODE	Mode	Description
0600	Free-running	The timer runs until it is stopped.
0b01	One-shot	The timer runs as long as LETI-MERn_REP0 != 0. LETIMERn_REP0 is decremented at each timer underflow.
0b10	Buffered	The timer runs as long as LETI-MERn_REP0 != 0. LETIMERn_REP0 is decremented on each timer underflow. If LETIMERn_REP1 has been written, it is loaded into LETIMERn_REP0 when LETI-MERn_REP0 is about to be decremented to 0.
0b11	Double	The timer runs as long as LETI-MERn_REP0 != 0 or LETIMERn_REP1 != 0. Both LETIMERn_REP0 and LETI-MERn_REP1 are decremented at each timer underflow.

The interrupt flags REP0 and REP1 in LETIMERn_IF are set whenever LETIMERn_REP0 or LETIMERn_REP1 are decremented to 0 respectively. REP0 is also set when the value of LETIMERn_REP1 is loaded into LETIMERn_REP0 in buffered mode.

### 21.3.3.3 Free-Running Mode

In free-running mode, the LETIMER acts as a regular timer and the repeat counter is disabled. When started, the timer runs until it is stopped using the STOP command bit in LETIMERn_CMD. A state machine for this mode is shown in Figure 21.2 LETIMER State Machine for Free-running Mode on page 739.

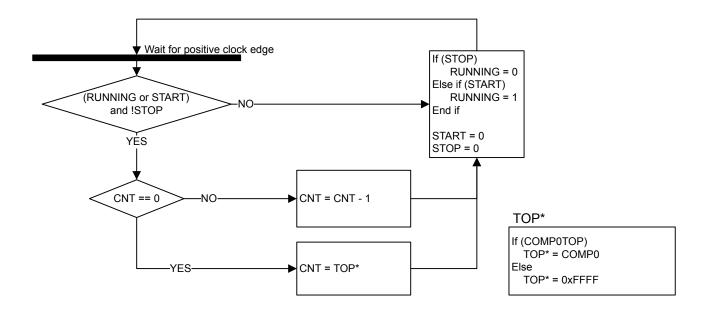

Figure 21.2. LETIMER State Machine for Free-running Mode

Note that the CLEAR command bit in LETIMERn_CMD always has priority over other changes to LETIMERn_CNT. When the clear command is used, LETIMERn_CNT is set to 0 and an underflow event will not be generated when LETIMERn_CNT wraps around to the top value or 0xFFFF. Since no underflow event is generated, no output action is performed. LETIMERn_REP0, LETIMERn_REP1, LETIMERn_COMP0 and LETIMERn_COMP1 are also left untouched.

#### 21.3.3.4 One-shot Mode

The one-shot repeat mode is the most basic repeat mode. In this mode, the repeat register LETIMERn_REP0 is decremented every time the timer underflows, and the timer stops when LETIMERn_REP0 goes from 1 to 0. In this mode, the timer counts down LETIMERn_REP0 times, i.e. the timer underflows LETIMERn_REP0 times.

**Note:** Write operations to LETIMERn_REP0 have priority over the timer decrement event. If LETIMERn_REP0 is assigned a new value in the same cycle as a timer decrement event occurs, the timer decrement will not occur and the new value is assigned.

LETIMERn_REP0 can be written while the timer is running to allow the timer to run for longer periods at a time without stopping. Figure 21.3 LETIMER One-shot Repeat State Machine on page 740 .

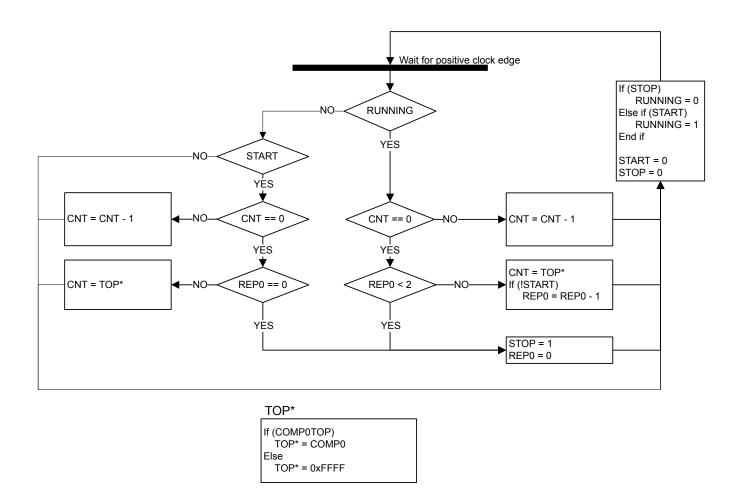

Figure 21.3. LETIMER One-shot Repeat State Machine

#### 21.3.3.5 Buffered Mode

The Buffered repeat mode allows buffered timer operation. When started, the timer runs LETIMERn_REP0 number of times. If LETIMERn_REP1 has been written since the last time it was used and it is nonzero, LETIMERn_REP1 is then loaded into LETIMERn_REP0, and counting continues the new number of times. The timer keeps going as long as LETIMERn_REP1 is updated with a nonzero value before LETIMERn_REP0 is finished counting down. The timer top value (LETIMERn_COMP0) may also optionally be buffered by setting BUFTOP in LETIMERn_CTRL.

If the timer is started when both LETIMERn_CNT and LETIMERn_REP0 are zero but LETIMERn_REP1 is non-zero, LETIMERn_REP1 is loaded into LETIMERn REP0, and the counter counts the loaded number of times.

Used in conjunction with a buffered top value, both the top and repeat values of the timer may be buffered, and the timer can for instance be set to run 4 times with period 7 (top value 6), 6 times with period 200, then 3 times with period 50.

A state machine for the buffered repeat mode is shown in Figure 21.4 LETIMER Buffered Repeat State Machine on page 741. REP1_{USED} shown in the state machine is an internal variable that keeps track of whether the value in LETIMERn_REP1 has been loaded into LETIMERn_REP0 or not. The purpose of this is that a value written to LETIMERn_REP1 should only be counted once. REP1_{USED} is cleared whenever LETIMERn_REP1 is written.

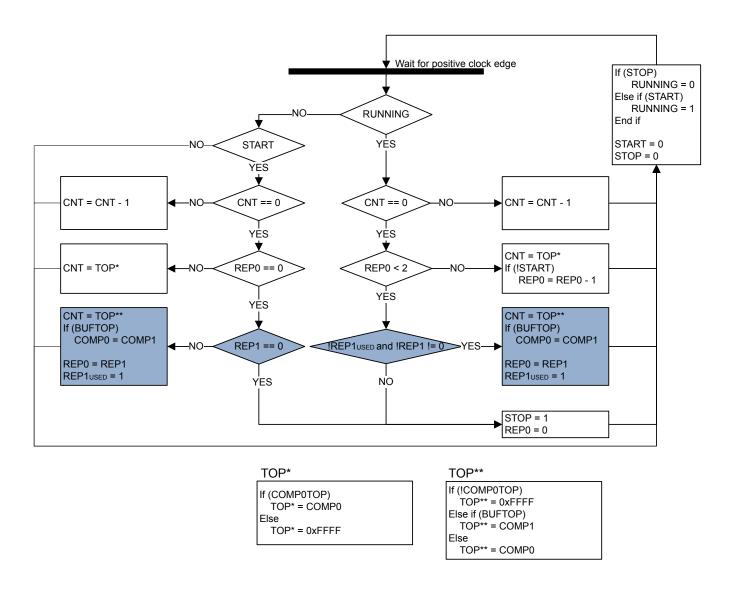

Figure 21.4. LETIMER Buffered Repeat State Machine

#### 21.3.3.6 Double Mode

The Double repeat mode works much like the one-shot repeat mode. The difference is that, where the one-shot mode counts as long as LETIMERn_REP0 is larger than 0, the double mode counts as long as either LETIMERn_REP0 or LETIMERn_REP1 is larger than 0. As an example, say LETIMERn_REP0 is 3 and LETIMERn_REP1 is 10 when the timer is started. If no further interaction is done with the timer, LETIMERn_REP0 will now be decremented 3 times, and LETIMERn_REP1 will be decremented 10 times. The timer counts a total of 10 times, and LETIMERn_REP0 is 0 after the first three timer underflows and stays at 0. LETIMERn_REP0 and LETIMERn_REP1 can be written at any time. After a write to either of these, the timer is guaranteed to underflow at least the written number of times if the timer is running. Use the Double repeat mode to generate output on both the LETIMER outputs at the same time. The state machine for this repeat mode can be seen in Figure 21.5 LETIMER Double Repeat State Machine on page 742.

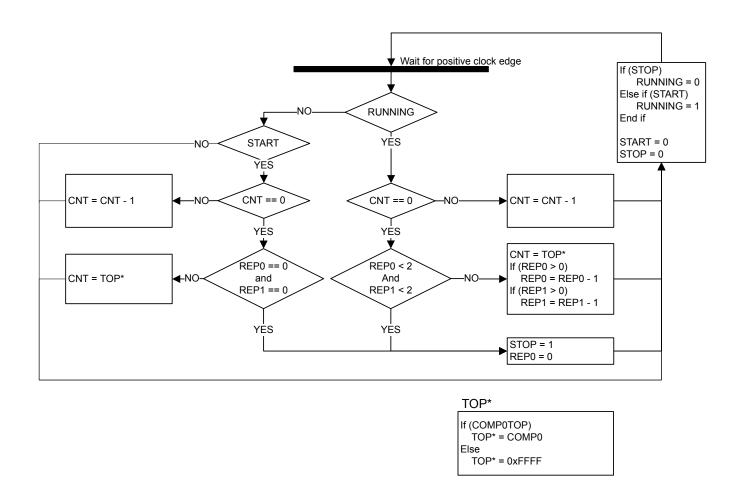

Figure 21.5. LETIMER Double Repeat State Machine

### 21.3.3.7 Clock Source

The LETIMER clock source and its prescaler value are defined in the Clock Management Unit (CMU). The LFACLK_{LETIMERn} has a frequency given by Figure 21.6 LETIMER Clock Frequency on page 742.

 $f_{LFACKL_LETIMERn} = 32768/2^{LETIMERn}$ 

Figure 21.6. LETIMER Clock Frequency

where the exponent LETIMERn is a 4 bit value in the CMU LFAPRESC0 register.

To use this module, the LE interface clock must be enabled in CMU_HFBUSCLKEN0, in addition to the module clock.

#### 21.3.3.8 PRS Input Triggers

The LETIMER can be configured to start, stop, and/or clear based on PRS inputs. The diagram showing the functions of the PRS input triggers is shown in Figure 21.7 LETIMER PRS Input Triggers on page 743.

There are 12 PRS inputs to the LETIMER. PRSSTARTSEL, PRSSTOPSEL, and PRSCLEARSEL select which PRS inputs are used to start, stop, and/or clear the LETIMER. PRSSTARTMODE, PRSSTOPMODE, and PRSCLEARMODE select which edge or edge(s) can trigger the start, stop, and/or clear action. The PRSSTARTEN, PRSSTOPEN, and PRSCLEAREN signals shown in the diagram are derived from the PRSSTARTMODE, PRSSTOPMODE, and PRSCLEARMODE fields; if the corresponding bit field is set to NONE, the feature is disabled.

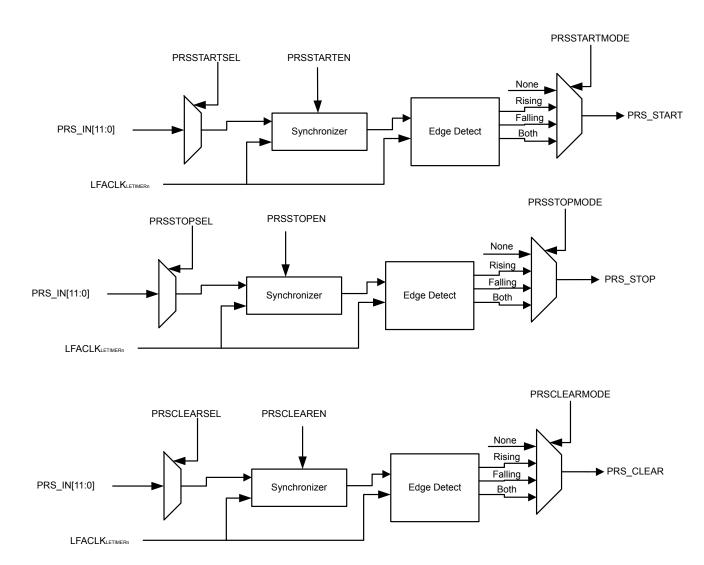

Figure 21.7. LETIMER PRS Input Triggers

#### 21.3.3.9 Debug

If DEBUGRUN in LETIMERn_CTRL is cleared, the LETIMER automatically stops counting when the CPU is halted during a debug session, and resumes operation when the CPU continues. Because of synchronization, the LETIMER is halted two clock cycles after the CPU is halted, and continues running two clock cycles after the CPU continues. RUNNING in LETIMERn_STATUS is not cleared when the LETIMER stops because of a debug-session.

Set DEBUGRUN in LETIMERn_CTRL to allow the LETIMER to continue counting even when the CPU is halted in debug mode.

#### 21.3.4 Underflow Output Action

For each of the repeat registers, an underflow output action can be set. The configured output action is performed every time the counter underflows while the respective repeat register is nonzero. In PWM mode, the output is similarly only changed on COMP1 match if the repeat register is nonzero. As an example, the timer will perform 7 output actions if LETIMERn_REP0 is set to 7 when starting the timer in one-shot mode and leaving it untouched.

The output actions can be set by configuring UFOA0 and UFOA1 in LETIMERn_CTRL. UFOA0 defines the action on output 0, and is connected to LETIMERn_REP0, while UFOA1 defines the action on output 1 and is connected to LETIMERn_REP1. The possible actions are defined in Table 21.2 LETIMER Underflow Output Actions on page 744.

**Table 21.2. LETIMER Underflow Output Actions** 

UF0A0/UF0A1	Mode	Description
0b00	Idle	The output is held at its idle value
0b01	Toggle	The output is toggled on LETIMERn_CNT underflow if LEIMERn_REPx is nonzero
0b10	Pulse	The output is held active for one clock cycle on LETIMERn_CNT underflow if LETI-MERn_REPx is nonzero. It then returns to its idle value
0b11	PWM	The output is set idle on LETIMERn_CNT underflow and active on compare match with LETIMERn_COMP1 if LETI-MERn_REPx is nonzero.

#### Note:

- For the Pulse and PWM modes, the outputs will return to their idle states regardless of the state of the corresponding LETI-MERn_REPx registers. They will only be set active if the LETIMERn_REPx registers are nonzero however.
- For free-running mode, LETIMERn_REP0 != 0 for output generation to be enabled.

The polarity of the outputs can be set individually by configuring OPOL0 and OPOL1 in LETIMERn_CTRL. When these are cleared, their respective outputs have a low idle value and a high active value. When they are set, the idle value is high, and the active value is low.

When using the toggle action, the outputs can be driven to their idle values by setting their respective CTO0/CTO1 command bits in LETIMERn_CTRL. This can be used to put the output in a well-defined state before beginning to generate toggle output, which may be important in some applications. The command bit can also be used while the timer is running.

Some simple waveforms generated with the different output modes are shown in Figure 21.8 LETIMER Simple Waveforms Output on page 745. For the example, REPMODE in LETIMERn_CTRL has been cleared, COMP0TOP also in LETIMERn_CTRL has been set and LETIMERn_COMP0 has been written to 3. As seen in the figure, LETIMERn_COMP0 now decides the length of the signal periods. For the toggle mode, the period of the output signal is 2(LETIMERn_COMP0 + 1), and for the pulse modes, the periods of the output signals are LETIMERn_COMP0+1. Note that the pulse outputs are delayed by one period relative to the toggle output. The pulses come at the end of their periods.

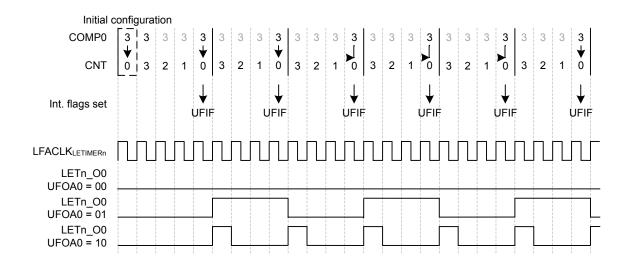

Figure 21.8. LETIMER Simple Waveforms Output

For the example in Figure 21.9 LETIMER Repeated Counting on page 745, the One-shot repeat mode has been selected, and LETI-MERn_REP0 has been written to 3. The resulting behavior is pretty similar to that shown in Figure 6, but in this case, the timer stops after counting to zero LETIMERn_REP0 times. By using LETIMERn_REP0 the user has full control of the number of pulses/toggles generated on the output.

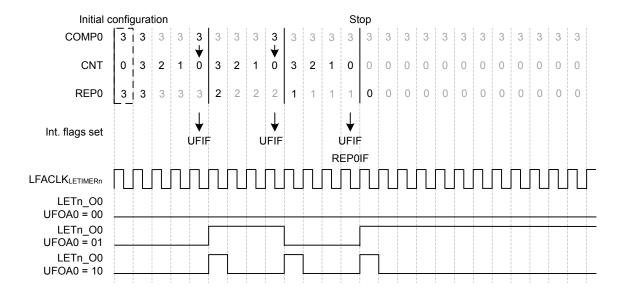

Figure 21.9. LETIMER Repeated Counting

Using the Double repeat mode, output can be generated on both the LETIMER outputs. Figure 21.10 LETIMER Dual Output on page 746 shows an example of this. UFOA0 and UFOA1 in LETIMERn_CTRL are configured for pulse output and the outputs are configured for low idle polarity. As seen in the figure, the number written to the repeat registers determine the number of pulses generated on each of the outputs.

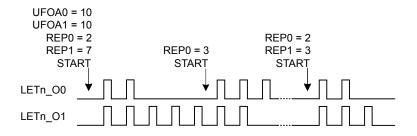

Figure 21.10. LETIMER Dual Output

### 21.3.5 PRS Output

The LETIMER outputs can be routed out onto the PRS system. Enabling the PRS connection can be done by setting SOURCESEL to LETIMERx and SIGSEL to LETIMERxCHn in PRS_CHx_CTRL. The PRS register description can be found in 15.5 Register Description

### 21.3.6 Examples

This section presents a couple of usage examples for the LETIMER.

#### 21.3.6.1 Triggered Output Generation

If both LETIMERn_CNT and LETIMERn_REP0 are 0 in buffered mode, and COMP0TOP and BUFTOP in LETIMERn_CTRL are set, the values of LETIMERn_COMP1 and LETIMERn_REP1 are loaded into LETIMERn_CNT and LETIMERn_REP0 respectively when the timer is started. If no additional writes to LETIMERn_REP1 are done before the timer stops, LETIMERn_REP1 determines the number of pulses/toggles generated on the output, and LETIMERn_COMP1 determines the period lengths.

As the RTC can be used via PRS to start the LETIMER, the RTC and LETIMER can thus be combined to generate specific pulse-trains at given intervals. Software can update LETIMERn_COMP1 and LETIMERn_REP1 to change the number of pulses and pulse-period in each train, but if changes are not required, software does not have to update the registers between each pulse train.

For the example in Figure 21.11 LETIMER Triggered Operation on page 747, the initial values cause the LETIMER to generate two pulses with 3 cycle periods, or a single pulse 3 cycles wide every time the LETIMER is started. After the output has been generated, the LETIMER stops, and is ready to be triggered again.

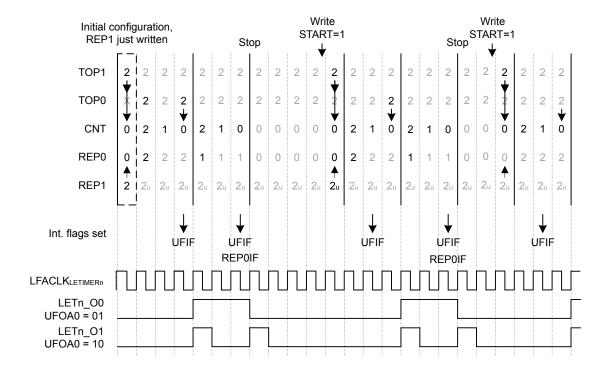

Figure 21.11. LETIMER Triggered Operation

#### 21.3.6.2 Continuous Output Generation

In some scenarios, it might be desired to make LETIMER generate a continuous waveform. Very simple constant waveforms can be generated without the repeat counter as shown in Figure 21.8 LETIMER Simple Waveforms Output on page 745, but to generate changing waveforms, using the repeat counter and buffer registers can prove advantageous.

For the example in Figure 21.12 LETIMER Continuous Operation on page 748, the goal is to produce a pulse train consisting of 3 sequences with the following properties:

- · 3 pulses with periods of 3 cycles
- · 4 pulses with periods of 2 cycles
- · 2 pulses with periods of 3 cycles

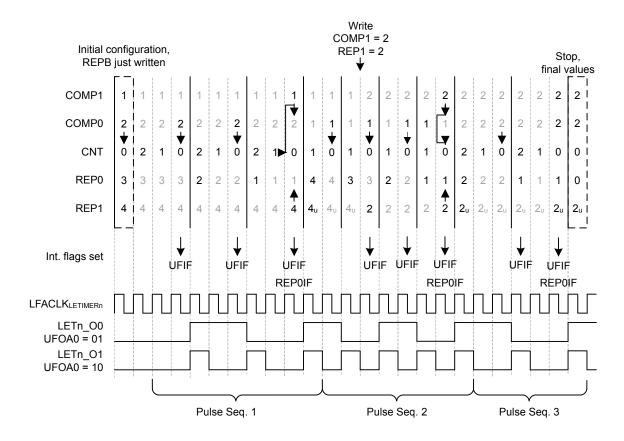

Figure 21.12. LETIMER Continuous Operation

The first two sequences are loaded into the LETIMER before the timer is started.

LETIMERn_COMP0 is set to 2 (cycles – 1), and LETIMERn_REP0 is set to 3 for the first sequence, and the second sequence is loaded into the buffer registers, i.e. COMP1 is set to 1 and LETIMERn_REP1 is set to 4.

The LETIMER is set to trigger an interrupt when LETIMERn_REP0 is done by setting REP0 in LETIMERn_IEN. This interrupt is a good place to update the values of the buffers. Last but not least REPMODE in LETIMERn_CTRL is set to buffered mode, and the timer is started.

In the interrupt routine the buffers are updated with the values for the third sequence. If this had not been done, the timer would have stopped after the second sequence.

The final result is shown in Figure 21.12 LETIMER Continuous Operation on page 748. The pulse output is grouped to show which sequence generated which output. Toggle output is also shown in the figure. Note that the toggle output is not aligned with the pulse outputs.

**Note:** Multiple LETIMER cycles are required to write a value to the LETIMER registers. The example in Figure 21.12 LETIMER Continuous Operation on page 748 assumes that writes are done in advance so they arrive in the LETIMER as described in the figure.

Figure 21.13 LETIMER LETIMERn_CNT Not Initialized to 0 on page 749 shows an example where the LETIMER is started while LETIMERn CNT is nonzero. In this case the length of the first repetition is given by the value in LETIMERn CNT.

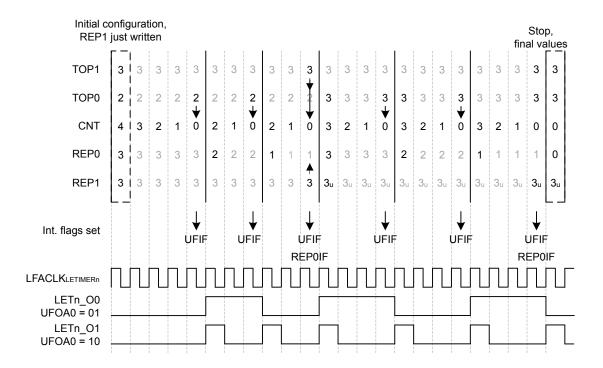

Figure 21.13. LETIMER LETIMERn CNT Not Initialized to 0

#### 21.3.6.3 PWM Output

There are several ways of generating PWM output with the LETIMER, but the most straight-forward way is using the PWM output mode. This mode is enabled by setting UFOA0 or UFOA1 in LETIMERn_CTRL to 3. In PWM mode, the output is set idle on timer underflow, and active on LETIMERn_COMP1 match, so if for instance COMP0TOP = 1 and OPOL0 = 0 in LETIMERn_CTRL, LETIMERn COMP0 determines the PWM period, and LETIMERn_COMP1 determines the active period.

The PWM period in PWM mode is LETIMERn_COMP0 + 1. There is no special handling of the case where LETIMERn_COMP1 > LETIMERn_COMP0, so if LETIMERn_COMP1 > LETIMERn_COMP0, the PWM output is given by the idle output value. This means that for OPOLx = 0 in LETIMERn_CTRL, the PWM output will always be 0 for at least one clock cycle, and for OPOLx = 1 LETIMERN CTRL, the PWM output will always be 1 for at least one clock cycle.

To generate a PWM signal using the full PWM range, invert OPOLx when LETIMERn_COMP1 is set to a value larger than LETI-MERn_COMP0.

### 21.3.6.4 Interrupts

The interrupts generated by the LETIMER are combined into one interrupt vector. If the interrupt for the LETIMER is enabled, an interrupt will be made if one or more of the interrupt flags in LETIMERn_IF and their corresponding bits in LETIMER_IEN are set.

### 21.3.7 Register Access

This module is a Low Energy Peripheral, and supports immediate synchronization. For description regarding immediate synchronization, the reader is referred to 4.3.1 Writing.

## 22. CRYOTIMER - Ultra Low Energy Timer/Counter

### **Quick Facts**

### What?

The CRYOTIMER is a timer capable of providing wakeup events/interrupts after deterministic intervals in all energy modes, including EM4.

### Why?

The CRYOTIMER enables the chip to remain in the lowest energy modes for long durations, while keeping track of time and being able to wake up at regular intervals, all with an absolute minimum current consumption.

### How?

Using a counter running on a prescaled Low Frequency Oscillator, the CRYOTIMER can provide periodic wakeup events with a very wide period range.

### 22.1 Introduction

The CRYOTIMER is a 32 bit counter which operates on a low frequency oscillator, and is capable of running in all energy modes. It can provide periodic wakeup events and PRS signals which can be used to wake up peripherals from any energy mode. The CRYOTIMER provides a very wide range of periods for the interrupts facilitating flexible ultra-low energy operation.

Because of its simplicity, the CRYOTIMER is a lower energy solution for periodically waking up the MCU compared to the RTCC.

#### 22.2 Features

- · 32 bit Counter
- · Works in all the energy modes
- · Only External and Power-On resets reset the CRYOTIMER
- · Interrupt/wake up event after deterministic intervals
- PRS Output
- · Debug mode
  - · Configurable to either run or stop when processor is stopped (break)

## 22.3 Functional Description

An overview of the CRYOTIMER is shown in Figure 22.1 CRYOTIMER Block Overview on page 768.

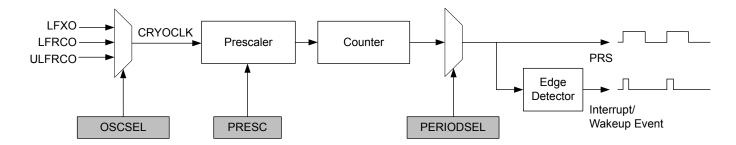

Figure 22.1. CRYOTIMER Block Overview

### 22.3.2 Operation

The desired low frequency oscillator for the CRYOTIMER operation can be selected by using OSCSEL in CRYOTIMER_CTRL. The selection must be made before enabling the CRYOTIMER, and it must be ensured that the selected oscillator is ready. This can be checked by observing LFXORDY or LFRCORDY (depending upon the oscillator selection) in CMU_STATUS. Note that the ULFRCO is always ready.

By default the CRYOTIMER is held in reset. It can be started by setting EN in CRYOTIMER_CTRL. The CRYOTIMER, when running, is reset by clearing EN.

The timer counts at a frequency determined by PRESC in CRYOTIMER_CTRL. This value should be set before the CRYOTIMER is enabled. Setting PRESC to 0 gives the maximum resolution, while higher values allow longer periods, see Table 22.1 CRYOTIMER Resolution vs Maximum Wakeup Event/Interrupt Period, F_{CRYOCLK} = 32768 Hz on page 769.

The 32-bit Counter provides 32 different options for selecting the duration between the Wakeup events. The selected duration is specified by CRYOTIMER PERIODSEL. It should be configured before the CRYOTIMER is enabled.

$$T_{WU} = (2^{PRESC} \times 2^{PERIODSEL})/f_{CRYOCLK}$$

Figure 22.2. Duration Between the CRYOTIMER Wakeup Events in Seconds

Table 22.1. CRYOTIMER Resolution vs Maximum Wakeup Event/Interrupt Period, FCRYOCLK = 32768 Hz

CRYOTIMER_CTRL_PRESC	Resolution, 2 ^{PRESC} /f _{CRYOCLK}	Maximum Wakeup event/Interrupt Period
DIV1	30.5 µs	36.4 hours
DIV2	61 µs	72.8 hours
DIV4	122 μs	145.6 hours
DIV8	244 μs	12 days
DIV16	488 μs	24 days
DIV32	977 μs	48 days
DIV64	1.95 ms	97 days
DIV128	3.91 ms	194 days

The 32-bit counter value of the CRYOTIMER can be read using the CRYOTIMER_CNT register.

The PRS output pulses of the CRYOTIMER are 1 CRYOCLK clock cycle wide. However, if the PRESC and PERIODSEL are both set to 0, the width of these pulses will be half CRYOCLK time period.

The CRYOTIMER wakeup events set the flag in the CRYOTIMER_IF. Interrupt on this event can be enabled by using the CRYOTIM-ER_IEN register.

The CRYOTIMER is always reset by the External Pin and Power-On resets. Additionally, by using EMU_CTRL, it can also be configured to reset by Watchdog, lockup, and system request resets.

Note: The CRYOTIMER configuration bits/registers should only be changed when EN in CRYOTIMER_CTRL is cleared.

### 22.3.3 Debug Mode

When the CPU is halted in debug mode, the CRYOTIMER can be configured to either continue to run or to be frozen. This is configured using DEBUGRUN in CRYOTIMER CTRL.

### 22.3.4 Energy Mode Availability

The CRYOTIMER is available in all energy modes. Wakeup from EM2 Deep Sleep and EM3 Stop to EM0 Active can be performed using the regular interrupt as discussed in 22.3.2 Operation. To generate wakeup events during EM4 Hibernate/Shutoff, EM4WU in CRYOTIMER_EM4WUEN must be set to 1. Since the interrupt flag serves as the wakeup source, it must be cleared by software after exiting a low energy mode. Refer to 10. EMU - Energy Management Unit for details on how to configure the EMU.

# 22.4 Register Map

The offset register address is relative to the registers base address.

# 23. VDAC - Digital to Analog Converter

#### **Quick Facts**

### What?

The VDAC is designed for low energy consumption, but can also provide very good performance. It can convert digital values to analog signals at up to 500 kilo samples/second with 12-bit accuracy.

### Why?

The VDAC can be used to generate accurate analog signals for sound, sensors and other applications, using only a limited amount of energy.

#### How?

The VDAC can generate high-resolution analog signals while the MCU is operating at low frequencies and with low total power consumption. Using DMA and a timer, the VDAC can be used to generate waveforms without any CPU intervention. The VDAC is available down to Energy Mode 3.

#### 23.1 Introduction

The Voltage Digital to Analog Converter (VDAC) can convert a digital value to an analog output voltage. The VDAC is fully differential rail-to-rail, with 12-bit resolution. It has two single ended output buffers which can be combined into one differential output. The VDAC may be used for a number of different applications such as sensor interfaces or sound output.

#### 23.2 Features

- · 500 ksamples/s operation
- · Two single ended output channels
  - · Can be combined into one differential output
- Integrated prescaler with division factor selectable between 1-128
- · Selectable voltage reference
  - · Internal low noise 2.5 V
  - Internal low noise 1.25 V
  - · Internal low power 2.5 V
  - Internal low power 1.25 V
  - AVDD
  - · External Pin Reference
- · Conversion triggers
  - · Data write
  - · PRS input
  - · Refresh timer
  - LESENSE
- · Automatic refresh timer
  - · Selection from 16-64 DAC_CLK cycles
  - · Individual refresh enable for each channel
- · Interrupt generation on buffer empty or finished conversion
  - · Separate interrupt flags for each channel
- · PRS output pulse on finished conversion
  - · Separate line for each channel
- · DMA request on buffer empty
  - · Separate request for each channel
- · Support for offset and gain calibration
- · Output to dedicated pins or APORT bus
- · Internal connections to ADC and ACMP
- · Sine generation mode
- · Asynchronous clocking mode

## 23.3 Functional Description

An overview of the VDAC module is shown in the figure below.

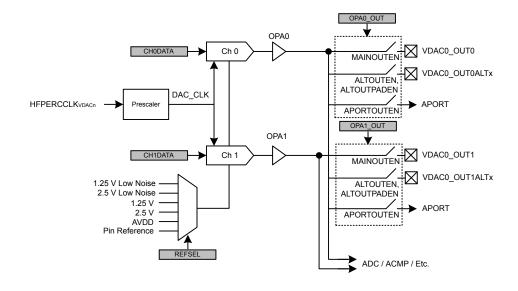

Figure 23.1. VDAC Overview

### 23.3.1 Power Supply

The VDAC module power ( $V_{OPA}$ ) is derived from the AVDD supply pin.

## 23.3.2 I/O Pin Considerations

The maximum usable analog signal that can be seen on external VDAC outputs depends on several factors: whether the signal is routed through the APORT, whether overvoltage is enabled, and on the IOVDD/AVDD supply voltages, as shown in the Table 23.1 Maximum Usable IO Voltage on page 779 table.

Table 23.1. Maximum Usable IO Voltage

VDAC Pin		Maximum IO Voltage (APORT UNUSED, OVT Enabled)	Maximum IO Voltage (APORT UN- USED, OVT Disabled)
VDAC External VREF Inputs	N/A	MIN(AVDD, IOVDD)	MIN(AVDD, IOVDD)
VDAC Outputs	MIN(AVDD, IOVDD)	MIN(AVDD, IOVDD + 2 V)	MIN(AVDD, IOVDD)

### 23.3.3 Enabling and Disabling a Channel

A VDAC channel is enabled by writing 1 to the CHxEN and disabled by writing 1 to CHxDIS in VDACn_CMD. The channel enabled status can be read by polling the CHxENS bit in VDACn_STATUS. This bit will go high immediately following a write to CHxEN. After disabling a channel the CHxENS bit will stay high until the VDAC channel is completely disabled.

Software should configure the VDAC before enabling a channel. Software *must not* write to any of the following registers while *either* CH0ENS or CH1ENS are set:

- VDACn_CTRL
- VDACn_CHxCTRL
- VDACn OPAxTIMER

A VDAC channel will not begin driving its output before it is enabled *and* has received a conversion trigger, see 23.3.4.3 Conversion Trigger. After a channel is enabled it will listen for trigger sources specified in TRIGMODE in VDACn_CHxCTRL. If TRIGMODE is set to SW, SWPRS or SWREFRESH and a value was written to CHxDATA or COMBDATA before enabling the channel a conversion will start immediately when the channel is enabled. When disabling a channel any pending triggers are flushed.

#### 23.3.4 Conversions

The VDAC consists of two channels (channel 0 and 1) with separate 12-bit data registers (VDACn_CH0DATA and VDACn_CH1DATA). These can be used to produce two independent single ended outputs or the channel 0 register can be used to drive both outputs in differential mode. The VDAC supports two conversion modes: continuous and sample/off.

### 23.3.4.1 Continuous Mode

In continuous mode the VDAC channels will drive their outputs continuously with the data in the VDACn_CHxDATA registers. A channel is configured in continuous mode by programming the CONVMODE bitfield in VDACn_CHxCTRL to CONTINUOUS. This mode will maintain the output voltage and no manual refresh is needed.

In continuous mode the SETTLETIME field in VDACn OPAxTIMER should be programmed to zero to achive the maximum update rate.

### 23.3.4.2 Sample/Off Mode

In sample/off mode the VDAC will only drive the output for a limited time per conversion. A channel is configured in sample/off mode by programming the CONVMODE bitfield in VDACn_CHxCTRL to SAMPLEOFF. How long the channel should drive the output can be controlled by programming the SETTLETIME field in the VDACn_OPAxTIMER register. The VDAC will drive the output for SETTLE-TIME f_{DAC_CLK} cycles before tristating the output again (and therefore if SETTLETIME is set to zero, the output will never be driven when using sample/off mode).

## 23.3.4.3 Conversion Trigger

Conversions can only be done while a channel is enabled, see 23.3.3 Enabling and Disabling a Channel.

If TRIGMODE is programmed to SW, SWPRS or SWREFRESH a conversion can be started by writing to the VDACn_CHxDATA register. The data registers are also mapped to a combined data register, VDACn_COMBDATA, where the data values for both channels can be written simultaneously. Writing to this register will trigger all enabled channels.

If TRIGMODE is programmed to PRS or SWPRS, a conversion can be started by an incoming pulse on the PRS channel selected in PRSSEL in VDACn_CHxCTRL. The PRSASYNC bit in VDACn_CHxCTRL determines if the VDAC expects a PRS pulse coming from a synchronous or asynchronous PRS producer.

If TRIGMODE is programmed to REFRESH or SWREFRESH a conversion will start on an overflow of the internal refresh timer. See 23.3.10 Refresh Timer.

If TRIGMODE is programmed to LESENSE a conversion will start when the LESENSE block sends a request. This setting needs to be selected whenever the channel is under LESENE control.

### 23.3.4.4 PRS Triggers

PRS triggers can be used to set a constant sample frequency, for instance by using a TIMER. In order to get a jitter-free sample rate, set DACCLKMODE to SYNC, set the CH0PRESCRST bit and clear the PRSASYNC bit. Note that this is only possible for channel 0.

The PRSASYNC bit tells whether the VDAC expects a synchronous PRS producer or not. When this bit is cleared, the PRS pulse must come from a synchronous producer and HFPERCLK must be running (this clock is turned off in EM2 and below). When PRSASYNC is set, the corresponding PRS channels should also bet configued as asynchronous (see the PRS chapter).

When either DACCLKMODE is set to ASYNC or the PRSASYNC bit is set, the sample frequency cannot be guaranteed to be jitter-free with respect to the PRS pulses.

The PRS frequency should never be higher than 0.5 MHz (the fastest possible sample rate). In addition the PRS frequency should not be higher than f_{HFPERCLK}/12 (in synchronous mode). If the PRS frequency is set too high, some PRS pulses will be dropped and the output can jitter.

## 23.3.5 Reference Selection

These voltage references are available and are selected by programming the REFSEL field in VDACn CTRL.

- Internal 1.25 V Low Noise Bandgap Reference
- · Internal 2.5 V Low Noise Bandgap Reference
- Internal 1.25 V Low Power Bandgap Reference
- · Internal 2.5 V Low Power Bandgap Reference
- AVDD

· External Pin

#### 23.3.6 Warmup Time and Initial Conversion

When a channel is first enabled it needs to warm up. This is performed automatically during the first conversion. The time required to warm up depends on the programmed DRIVESTRENGTH field in VDACn_OPAx_CTRL. In Table 23.2 VDAC Warmup Time on page 781 the minimum WARMUPTIME field for each drive strength is specified. Software is responsible for programming the correct value to WARMUPTIME before enabling a channel. If the time is programmed too short, an undefined voltage may be output until the VDAC settles.

The CHxWARM bits in VDACn STATUS are set when the warmup period has completed.

A consequence of the warmup period is that in continuous mode, the first conversion might take longer than the following conversions. In order to make sure all samples have the same timing, perform a dummy conversion to make the VDAC settle to a known voltage first.

Table 23.2. VDAC Warmup Time

DRIVESTRENGTH	WARMUPTIME
0	100 μs
1	85 µs
2	8 µs
3	8 µs

### 23.3.7 Analog Output

The output selection for each VDAC channel is configured in the VDACn_OPAx_OUT registers. Each VDAC channel has its own main output pin, VDACn_OUTx, that can be enabled with MAINOUTEN. In addition, several alternate outputs can be selected. These are enabled by first setting ALTOUTEN and then setting the corresponding bit(s) in ALTOUTPADEN. The VDAC output can also be routed to APORT by setting APORTOUTEN and configuring the APORTOUTSEL field to select the desired APORT.

The VDAC outputs also have direct internal connections to ADCs and ACMPs. These outputs are always enabled and can be selected by configuring the input selection for the ADC/ACMP.

In sample/off mode the VDAC will only drive the output for the duration programmed in SETTLETIME (in VDACn_OPAx_TIMER register) for each incoming conversion trigger. In continuous mode the VDAC will continue to drive the output until the channel is disabled. However, note that also in this mode a conversion trigger is needed before the output is enabled. See 23.3.3 Enabling and Disabling a Channel and 23.3.4.3 Conversion Trigger.

## 23.3.8 Output Mode

The two VDAC channels can act as two separate single ended channels or be combined into one differential channel. This is selected through the DIFF bit in VDACn_CTRL.

### 23.3.8.1 Single Ended Output

When operating in single ended mode, the channel 0 output is on VDACn_OUT0 and the channel 1 output is on VDACn_OUT1. The output voltage can be calculated using Figure 23.2 VDAC Single Ended Output Voltage on page 781

V_{OUT} = V_{VDACn OUTx} - V_{SS}= V_{ref} x CHxDATA/4095

Figure 23.2. VDAC Single Ended Output Voltage

where CHxDATA is a 12-bit unsigned integer.

## 23.3.8.2 Differential Output

When operating in differential mode, both VDAC outputs are used. The differential conversion uses VDACn_CH0DATA as source. The positive output is on VDACn_OUT1 and the negative output is on VDACn_OUT0. Since the output can be negative, it is expected that

the data is written in 2's complement form with the MSB of the 12-bit value being the signed bit. The output voltage can be calculated using Figure 23.3 VDAC Differential Output Voltage on page 782:

V_{OUT} = V_{VDACn OUT1} - V_{VDACn OUT0} = V_{ref} x CH0DATA/2047

## Figure 23.3. VDAC Differential Output Voltage

where CH0DATA is a 12-bit signed integer. The common mode voltage is  $V_{ref}/2$ .

When using differential mode, the user must make sure that both channels are set up identically. I.e. VDACn_CH0CTRL and VDACn_CH1CTRL must be programmed to identical values (with the exception that the PRSSEL bitfield is allowed to be programmed differently for usage together with the OUTENPRS feature). Similarly the user must program VDACn_OPA0TIMER and VDACn_OPA1TIMER to identical values.

### 23.3.9 Async Mode

The VDAC is default clocked from HFPERCLK, which is automatically turned off in EM2/3. In order to allow VDAC operation in EM2/3 an internal oscillator can be selected for the VDAC by setting the DACCLKMODE bitfield in VDACn_CTRL to ASYNC. Before entering EM2/3 software must make sure the channel is enabled first by polling CHxENS in VDACn_STATUS. Entering EM2/3 with an enabled VDAC channel while DACCLKMODE is set to SYNC is a programming error and will lead to EM23ERRIF getting set to 1.

In asynchronous mode both VDAC channels are not necessarily triggered synchronous to each other and therefore the user should not assume that e.g. PRS, refresh or VDACn_COMBDATA based conversion triggers are observed by both channels at the same time. In differential mode both channels will operate in lock step, even while using the asynchronous clocking mode.

#### 23.3.10 Refresh Timer

The VDAC includes an internal refresh timer. The refresh timer is automatically started if a channel selects either REFRESH or SWRE-FRESH for TRIGMODE and the channel is enabled. The refresh timer will count the number of f_{DAC_CLK} cycles programmed in RE-FRESHPERIOD before wrapping and generating a conversion trigger.

#### 23.3.11 Clock Prescaling

The VDAC has an internal clock prescaler, which can divide the input clock by any factor between 1 and 128, by setting the PRESC field in VDACn_CTRL. The resulting DAC_CLK is used by the converter core and the frequency is given by Figure 23.4 VDAC Clock Prescaling on page 782:

$$f_{DAC CLK} = f_{IN CLK} / (PRESC + 1)$$

## Figure 23.4. VDAC Clock Prescaling

where  $f_{IN_CLK}$  is the input clock frequency. The  $f_{DAC_CLK}$  must be programmed to be at most 1 MHz. When the DACCLKMODE is set to SYNC, the input clock frequency is  $f_{HFPERCLK}$ . When DACCLKMODE is set to ASYNC, an internal 12Mhz oscillator is used. In this mode it is required that the PRESC field be program to 11 or higher.

The prescaler runs continuously when either of the channels are enabled. When running with a prescaler setting higher than 0, there will be an unpredictable delay from the time the conversion was triggered to the time the actual conversion takes place. This is because the conversions are controlled by the prescaled clock and the conversion can arrive at any time during a prescaled clock (DAC_CLK) period. A second reason for unpredictable delay between a trigger and the associated conversion is that the activity on one channel can impact whether the VDAC reference is warm or not and therefore it can impact whether warmup is required when using the other channel. The uncertainty related to the clock prescaler can be addressed by using CH0PRESCRST. If the CH0PRESCRST bit in VDACn_CTRL is set, the prescaler will be reset every time a conversion is triggered on channel 0. This leads to a predictable latency between channel 0 trigger and conversion (assuming the warmup sequence is deterministic as well). If channel 0 is used in continuous mode, the warmup sequence will only apply to its first conversion and software can use the CH0WARM status bit to determine if the VDAC has warmed up.

### 23.3.12 High Speed

The VDAC is able to do conversions up to 400 ksamples/s. In order to reach the maximum conversion rate it is recommended to configure the VDAC in the following way:

- 1. Make f_{DAC CLK} 1 Mhz
- 2. Set TRIGMODE to SW
- 3. Program SETTLETIME in OPAx_TIMER to 0

- 4. Set up a DMA transfer from a buffer in RAM to CHxDATA
- 5. Set CONVMODE to CONTINUOUS

### 23.3.13 Sine Generation Mode

The VDAC contains an automatic sine-generation mode, which is enabled by setting the SINEMODE bit in VDACn_CTRL. In this mode, the VDAC data is overridden with a conversion data taken from a sine lookup table. The sine signal is controlled by the PRS line selected by CH0PRSSEL in VDACn_CH0CTRL. When the line is high, a sine wave will be produced. Each period, starting at 0 degrees, is made up of 16 samples and the frequency is given by Figure 23.5 VDAC Sine Generation on page 783. In case OUTENPRS equals 1, lowering the PRS line selected by CH0PRSSEL will reset the sine output to 0 degrees resulting in a voltage of Vref/2 on the output channel. In case OUTENPRS equals 0, lowering the PRS line selected by CH0PRSSEL will stop progress of the sine wave at the sample currently being output (and the sine will therefore not be reset to 0 degrees when raising the PRS line again).

$$f_{sine} = f_{HFPERCLK} / 32 x (PRESC + 1)$$

Figure 23.5. VDAC Sine Generation

Sine mode is supported only for the fastest configuration of the VDAC in continuous mode. Therefore the CONVMODE bitfield needs to be set to CONTINUOUS and the SETTLETIME bitfield in VDACn_OPAxTIMER need to be programmed to zero for the used channel(s) in order to use sine generation mode. The TRIGMODE bitfield needs to be programmed to PRS for any channel used for sine generation mode. The other trigger modes are not supported.

The SINE wave will be output on channel 0 and therefore requires that this channel is enabled by writing 1 to CH0EN in the VDACn_CMD register. If DIFF is set in VDACn_CTRL, the sine wave will be output on both channels, but inverted. Note that when OUTENPRS in VDACn_CTRL is set, the sine output will be reset to 0 degrees when the PRS line selected by CH1PRSSEL is low.

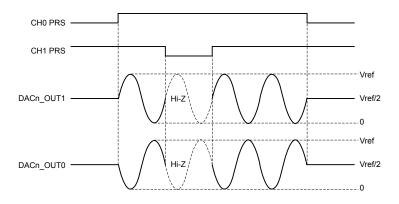

Figure 23.6. VDAC Sine Mode

### 23.3.14 Interrupt Flags

The VDAC has several interrupt flags, indicating state transitions and error conditions.

In addition to the VDAC interrupt flags the VDAC registers contain interrupt flags for the OPAMP modules. See The OPAMP chapter for more information on these flags.

### 23.3.14.1 Conversion Done

The Conversion Done (CHxCD) interrupt flags are set when a conversion is complete. The flags are set after a channel has driven the output with the new code for the time programmed in SETTLETIME in VDACn_OPAxTIMER.

### 23.3.14.2 Buffer Level

The Buffer Level (CHxBL) interrupt flags are set when there is space available in CHxDATA. These flags are initially set, get cleared when CHxDATA is written and set again when the value is used for a conversion.

#### 23.3.14.3 Overflow/Underflow

If CHxDATA is written to while CHxBL is cleared, the channel overflow flag (CHxOF) will be set. If a new conversion is triggered (e.g. via PRS) before data is written to CHxDATA (CHxDATA is empty) the channel underflow flag (CHxUF) will be set.

### 23.3.14.4 EM2/3 Sleep Error

The VDAC can only operate in EM2/3 when DACCLKMODE is set to ASYNC. If EM2 or EM3 is entered while a channel is enabled and DACCLKMODE is set to SYNC the EM23ERRIF flag will be set.

### 23.3.15 PRS Outputs

The VDAC has two PRS outputs which will carry a one cycle (HFPERCLK) high pulse when the corresponding channel has finished a conversion. Only available when DACCLKMODE is set to SYNC.

### 23.3.16 DMA Request

Each channel sends a DMA request when there is space in the channel's data register (VDACn_CHxDATA). These registers are initially empty and also become empty every time a conversion is triggered. The request is cleared when VDACn_CHxDATA is written.

### 23.3.17 LESENSE Trigger Mode

The VDAC can be controlled by LESENSE by programming the TRIGMODE field in VDACn_CHxCTRL to LESENSE. In LESENSE mode the conversion data can come from either VDACn_CHxDATA registers or LESENSE registers, depending on the LESENSE configuration. The trigger events are also controlled by the LESENSE state machine. See the LESENSE chapter for more information.

### 23.3.18 Opamps

The VDAC includes a set of highly configurable opamps that can be accessed with the VDAC registers. OPA0 and OPA1 is used for the output stages of the two VDAC channels, but can be used as standalone opamps if the VDAC channels are not in use. Opamps with higher numbers are completely standalone. For a detailed description see the OPAMP chapter.

### 23.3.19 Calibration

The VDAC contains a calibration register, VDACn_CAL, where calibration values for both offset and gain correction can be written. The required (gain) calibration values depend on the chosen reference and on whether the main or alternative VDAC output is used. The Device Information page provides the required trim values depending on reference choice and output selection in the DEVINFO_VDACnMAINCAL, DEVINFO_VDACnALTCAL, and DEVINFO_VDACnCH1CAL locations.

The OPAMPs contain a calibration register, VDACn_OPAx_CAL, where calibration values for both offset and gain correction can be written. The required calibration settings depend on the chosen DRIVESTRENGTH. The required calibration values can be found in the Device Information pages. For a given OPAMP x, the calibration settings for DRIVESTRENGTH n can be found in DEVINFO_OPAx-CALn.

## 23.3.19.1 Channel 1 Calibration

For channel 1, the factory calibration values are only accurate for the main output. When using the alternative outputs or APORT, the error on the output may be larger than the data sheet values (even when loading values from DEVINFO_VDACn_ALTCAL). To get accurate output from channel 1, either use the main output or perform manual calibration.

## 23.3.19.2 Manual Calibration

To manually calibrate the VDAC:

- 1. Enable CH0 and CH1 in their desired modes
- 2. Set both channel outputs to 80% of full-scale by setting VDACn CHxDATA = 0xCCC
- 3. Measure CH0 output and sweep VDACn_CAL.GAINERRTRIM until the smallest calibration error is found
- 4. Measure CH1 output and sweep VDACn CAL.GAINERRTRIMCH1 until the smallest calibration error is found

The calibration error is given by

$$e = abs(V_{out}/(V_{REF} * 0.8) - 1)$$

## Figure 23.7. Calibration Error

where  $V_{\text{out}}$  is the measured voltage at the pin and  $V_{\text{REF}}$  is the reference voltage.

Note that even if only CH1 is going to be used, the full calibration procedure should be followed. It is permissible to skip CH1 calibration if only CH0 is used. The following parameters influence the calibration. A change in any of these might require a re-calibration:

- VDACn CTRL.REFSEL
- VDACn OPAx OUT.MAINOUTEN
- VDACn_OPAx_OUT.ALTOUTEN
- VDACn_OPAx_CTRL.DRIVESTRENGTH

### 23.3.20 Warmup Mode

If the WARMUPMODE field in VDACn_CTRL is set to KEEPINSTANDBY, the VDAC keeps internal bias currents running between conversions. It does not reduce the startup time, but it can help reduce noise from the VDAC to other analog peripherals, like the ADC or ACMP.

APORT connected devices to monitor the same APORT bus simultaneously by allowing the OPAx to not master the selected bus. When 1, the determination is expected to be from another peripheral, and the OPAx only passively looks at the bus. When 1, the selection of channel for a selected bus is ignored (the bus is not), and is whatever selection the external device mastering the bus has configured for the APORT bus.

Value			Description
0			Bus mastering enabled
1			Bus mastering disabled
APORTXMASTER-	0	RW	APORT Bus Master Disable

Determines if the OPAx will request the APORT bus X with POSSEL, NEGSEL or APORTOUTSEL. This bit allows multiple APORT connected devices to monitor the same APORT bus simultaneously by allowing the OPAx to not master the selected bus. When 1, the determination is expected to be from another peripheral, and the OPAx only passively looks at the bus. When 1, the selection of channel for a selected bus is ignored (the bus is not), and is whatever selection the external

#### 24. OPAMP - Operational Amplifier

#### **Quick Facts**

#### What?

The opamps are low power amplifiers with a high degree of flexibility targeting a wide variety of standard opamp application areas. With flexible gain and interconnection built-in, they can be configured to support multiple common opamp functions. All pins are available externally for filter configurations. Each opamp has a rail-to-rail input and a rail-to-rail output.

#### Why?

The opamps are included not only to save energy on a PCB compared to standalone opamps but also to reduce system cost by replacing external opamps.

#### How?

Two of the opamps are made available as part of the VDAC, while the other opamps are standalone. In addition to popular differential-to-single ended and differential-to-differential driver modes, an ADC unity gain buffer mode configuration makes it possible to isolate kickback noise. The opamps can also be configured as a multi-step cascaded PGA, and for all of the built-in modes no external components are necessary.

#### 24.1 Introduction

The opamps are highly configurable general purpose opamps, suitable for simple filters and buffer applications. The 3 opamps can be configured to support various operational amplifier functions through a network of muxes with possibilities of selecting ranges of on-chip non-inverting and inverting gain configurations and selecting between outputs to various destinations. The opamps can also be configured with external feedback in addition to supporting cascade connections between two or three opamps. The opamps are rail-to-rail in and out. A user selectable mode has been added to optimize linearity, in which case the input voltage to the opamp is restricted to a range between VSS and AVDD-1.2V.

#### 24.2 Features

- · 3 individually configurable opamps
- · Opamps support rail-to-rail inputs and outputs
- · Supports the following functions
  - · General opamp mode
  - · Voltage follower unity gain
  - · Inverting input PGA
  - · Non-inverting PGA
  - · Cascaded inverting PGA
  - · Cascaded non-inverting PGA
  - · Two opamp differential amplifier
  - Three opamp differential amplifier
  - · Dual buffer ADC driver
- · Programmable gain
- · Programmable drive strength
- · Programmable start delay, warmup and settle time
- · Connection to APORT
- · Enable / Disable via PRS

· Output status to PRS

#### 24.3 Functional Description

The 3 opamps can be configured to perform various opamp functions through a network of muxes. An overview of the opamps are shown in Figure 24.1 OPAMP System Overview on page 822. Two of the 3 opamps are part of the VDAC, while the others are standalone. The outputs of the opamps can be routed to the ADC and ACMP. All 3 opamps can also take input from pins. Since OPA0 and OPA1 are part of the VDAC, special considerations needs to be taken when both VDAC channel 0/channel 1 and OPA0/OPA1 are used. For detailed explanation, refer to 24.3.5 Opamp VDAC Combination.

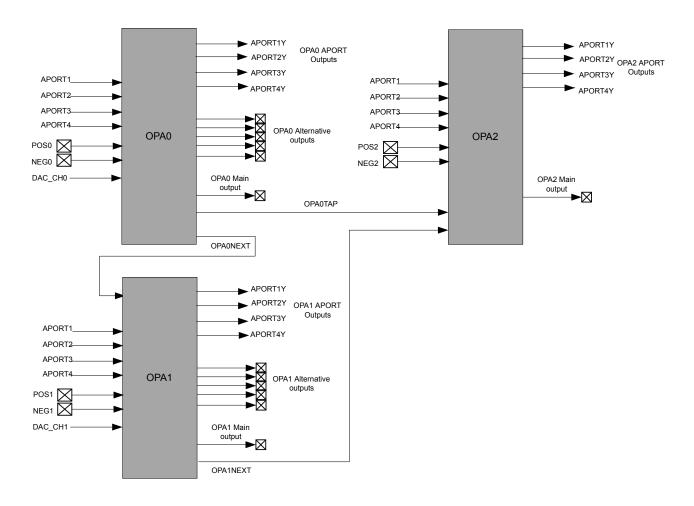

Figure 24.1. OPAMP System Overview

There is a set of input muxes for each opamp, making it possible to select various input sources. A more detailed view of the 3 opamps, including the mux network is shown in Figure 24.2 OPAMP Overview on page 823. The POSSEL mux connected to the positive input makes it possible to select a pin, another opamp output, or tap from the resistor network. Similarly, the NEGSEL mux on the negative input makes it possible to select a pin or a feedback path as its source. The feedback path can be unity gain, 3x gain, or selected from the resistor network for programmable gain. Each opamp has several outputs, a main output, an alternative output network, APORT output and a next output. These outputs make it possible to route the output to a pin, another opamp input, the ADC, the ACMP, or into the feedback path. For details regarding configuring the outputs, see 24.3.1.8 Output Configuration. In addition, there is also a mux to configure the resistor ladder for connection to VSS, a pin, or another opamp output.

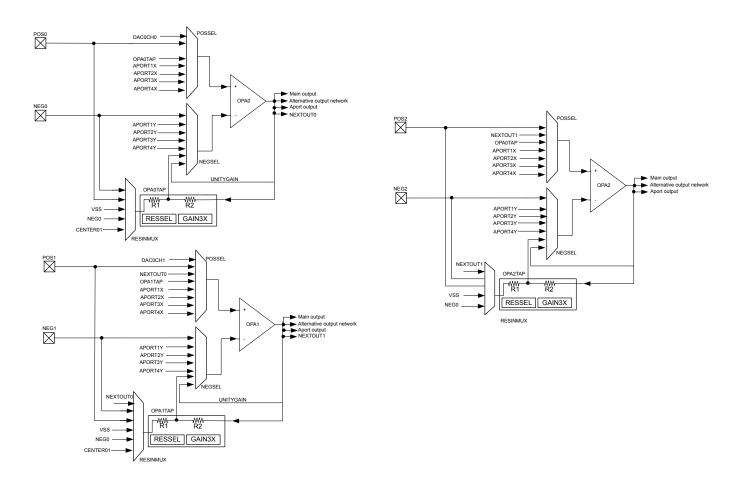

Figure 24.2. OPAMP Overview

#### 24.3.1 Opamp Configuration

Since two of the 3 OPAMPs (OPA0, OPA1) are part of the VDAC, the opamp configuration registers are located in the VDAC.

Each OPAMP can be enabled by setting OPAxEN in VDACn_CMD and can be disabled by setting OPAxDIS in VDACn_CMD. The enabled status of each OPAMP can be read by polling the OPAxENS bit in VDACn_STATUS. OPAxENS goes high immediately after an OPAxEN is written and goes low when OPAxDIS is written and after OPAMP is completely disabled.

Software must not write to the following registers while OPAxENS set.

- VDACn OPAx CTRL
- VDACn OPAx TIMER
- VDACn_OPAx_MUX

#### 24.3.1.1 Enable Sources

Opamp can be enabled either with software or PRS. The default source is software. Setting PRSEN to 1 in VDACn_OPAx_CTRL enables PRS mode. In PRS mode, opamp has two options, which are selectable with PRSMODE in VDACn_OPAx_CTRL. If PRSMODE is configured to TIMED, opamp is turned on the positive edge of PRS and stays on until PRS goes low. If PRSMODE is configured to PULSED, opamp is turned on the positive edge of PRS and stays on based on the timer configurations in VDACn_OPAxTIMER. The PRS channel is selected by PRSSEL in VDACn_OPAx_CTRL.

#### 24.3.1.2 Warmup Time

When an opamp is enabled some initialization time is required. The warm up period is programmable with WARMUPTIME in VDACn OPAx TIME. The OPAxWARM bit in VDACn STATUS are set when the warmup period has completed.

The warm up period depends on the selected DRIVESTRENGTH in VDACn_OPAx_CTRL.

Table 24.1. OPAMP Warmup Time

DRIVESTRENGTH	WARMUPTIME (µs)
0	100
1	85
2	8
3	6

#### 24.3.1.3 Settle Time

After an opamp is enabled and the warmed-up time has elapsed the output settles externally. The settle period is programmable with SETTLETIME in VDACn_OPAx_TIME. The OPAxOUTVALID bit in VDACn_STATUS is set when the settle period has completed. When in use by the VDAC the default settling time is used.

The settling period depends on the load at opamp output and DRIVESTRENGTH of the opamp. Table 24.2 OPAMP Settling Time on page 824 specifies SETTLETIME settings for a load of 1KOhm and 75pF.

Table 24.2. OPAMP Settling Time

DRIVESTRENGTH	SETTLETIME (µs)
0	60
1	25
2	3
3	1

#### 24.3.1.4 Startup Delay

Each opamp has an option to delay the warm up period. The startup delay is programmable with STARTDLY in VDACn_OPAx_TIME. If STARTDLY is programmed to a non-zero value, the opamp is warmed up after STARTDLY+WARMUPTIME, and the output settles after STARTDLY+WARMUPTIME+SETTLETIME.

### 24.3.1.5 Power Supply

The opamp module power (V_{OPA}) is derived from the AVDD supply pin.

#### 24.3.1.6 I/O Pin Considerations

The maximum usable analog signal that can be applied to external opamp inputs (or seen on external opamp outputs) depends on several factors: whether the signal is routed through the APORT, whether High Linearity mode is used, whether overvoltage is enabled, and on the IOVDD/AVDD supply voltages, as shown in the Table 24.3 Maximum Usable IO Voltage on page 824 table.

Table 24.3. Maximum Usable IO Voltage

Opamp Pin	Maximum IO Voltage (APORT USED and OVT Enabled/ Disabled)		Maximum IO Voltage (APORT UN- USED, OVT Disabled)
Opamp Inputs - Normal Mode	MIN(AVDD, IOVDD)	MIN(AVDD, IOVDD)	MIN(AVDD, IOVDD)
Opamp Outputs	MIN(AVDD, IOVDD)	MIN(AVDD, IOVDD + 2 V)	MIN(AVDD, IOVDD)

#### 24.3.1.7 Input Configuration

The inputs to the opamps are controlled through a set of input muxes. The mux connected to the positive input is configured by the POSSEL bit-field in the VDACn_OPAx_MUX register. Similarly, the mux connected to the negative input is configured by setting the NEGSEL bit-field in VDACn_OPAx_MUX. The input into the resistor ladder can be configured by setting the RESINMUX bit-field in VDACn_OPAx_MUX.

## 24.3.1.8 Output Configuration

Each opamp has three outputs: the main output, an alternative output network with lower drive strength, and an APORT output with low drive strength. These three outputs can be configured as shown in Figure 24.3 Opamp Output Stage Overview on page 825. The main output can be used to drive the main output by setting MAINOUTEN in VDACn_OPAx_OUT. The alternative output can drive the alternative output network by setting ALTOUTEN in VDACn_OPAx_OUT. The APORT output can drive the APORT selection mux by setting APORTOUTEN in VDACn_OPAx_OUT.

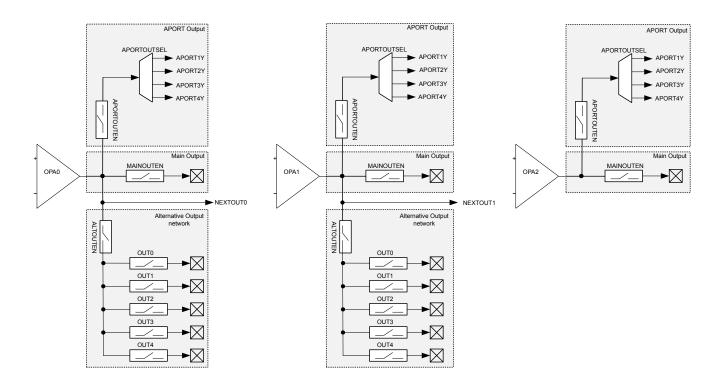

Figure 24.3. Opamp Output Stage Overview

The alternative output network consists of connections to pins and a connection to the next opamp. The connections to pins can be individually enabled by configuring ALTOUTPADEN in te VDACn_OPAx_OUT register. For cascaded opamp configurations, each opamp has a NEXTOUT connection.

The opamp outputs can also be routed to APORT1Y, APORT2Y, APORT3Y, and APORT4Y. The APORT channel can be selected by configuring APORTOUTSEL in VDACn OPAx OUT.

The opamps are also routed internally to the ADC. OPA0 and OPA1 are routed through the POSMUX of the ADC, and OPA2 is routed through the NEGMUX of the ADC. See 26.3.7 Input Selection in the ADC chapter for information on how to configure the ADC input mux.

In addition, OPA0 and OPA1 are internally routed to both the POSMUX and NEGMUX of ACMP. See 25.3.6 Input Selection in the ACMP chapter for information on how to configure the ACMP input mux.

The main and alternate outputs of each opamp can be shorted together by setting the SHORT bit-field in VDACn_OPAx_OUT.

#### 24.3.1.9 Gain Programming

The feedback path of each mux includes a resistor ladder that can be used to select a set of gain values. Gain is configured by the RESSEL bit-field located in the VDACn_OPAx_MUX register. Gain values are determined by the resistor ladder based on ratio of R2/R1. It is also possible to bypass the resistor ladder in unity gain mode. In addition, there is also a preconfigured resistor ladder with

3X gain. The 3x gain resistor ladder is enabled by setting GAIN3X in VDACn_OPAx_MUX. By default all opamps are configured in 3x gain mode. When using RESSEL, GAIN3X should be set to zero.

#### 24.3.1.10 Offset Calibration

Each opamp has a calibration register, VDACn_OPAx_CAL, where calibration values for both offset and gain correction can be written. The required calibration settings depend on the chosen DRIVESTRENGTH. The default calibration settings stored in VDACn_OPAx_CAL are for DRIVESTRENGTH=2. If an opamp is being reconfigured, the required calibration settings for DRIVESTRENGTH=n can be found in DEVINFO_OPAxCALn. Offsets can be programmed through the OFFSETP and OFFSETN bitfields of VDACn_OPAx_CAL.

#### 24.3.1.11 Disabling of Rail-to-Rail Operation

Each opamp can have its input rail-to-rail stage disabled by setting the HCMDIS in VDACn_OPAx_CTRL. Disabling the rail-to-rail input stage improves linearity of the opamp, thus improving the total harmonic distortion (THD) at the cost of reduced input signal swing.

#### 24.3.1.12 Unity Gain Bandwidth Scaling

Unity gain bandwidth of an opamp can be scaled setting the INCBW bit in VDACn_OPAx_CTRL. Note that this setting is used only when closed loop gain is greater than 3X. With this setting is enabled, the opamp is not unity gain stable.

#### 24.3.1.13 Opamp Output Scaling

Opamp output drive strength is scaled by one half when the OUTSCALE bit in VDACn_OPAx_CTRL is set.

#### 24.3.2 Interrupts and PRS Output

Each opamp has an interrupt flag OPAxOUTVALID in VDACn_IF that is set when the output is settled externally at the load. An interrupt will be requested if the OPAxOUTVALID interrupt flag in VDACn_IF is set and enabled by the OPAxOUTVALID bit in VDACn_IEN.

The OPAxERRPRSMODE interrupt flag in VDACn_IF indicates a protocol error when the opamp is triggered in PRS TIMED mode. This flag is set if the negative edge of the PRS pulse came before the output to opamp is valid. The interrupt flag is enabled by the OPAxERPRSMODE bit in VDACn_IEN.

An interrupt can also be requested when an APORT bus conflict occurs if the OPAxAPORTCONFLICT interrupt flag in VDACn_IF is set and enabled through by the OPAxAPORTCONFLICT bit in VDACn_IEN.

One of two aynchronous PRS outputs can be enabled for each opamp by setting PRSOUTMODE in VDACn_OPAx_CTRL. If PRSOUTMODE is WARM, opamp warm-up status is available. If PRSOUTMODE is OUTVALID, opamp output valid status is available.

### 24.3.3 APORT Request and Conflict Status

The opamps are connected to pins through the APORT system. To help debug over-utilization of APORT resources, the opamps provide request and conflict status information. The request status of APORT buses is visible through the DACn_OPAx_APORTREQ register.

If an APORT bus conflict occurs, it is reported in the DACn_OPAx_APORTCONFLICT register. An APORT conflict occurs if an opamp requests the same bus at the same time as another analog peripheral. In addition an APORT conflict is reported if any two of NEGSEL, POSSEL or APORTOUTSEL are configured to request the same APORT bus.

It is possible for the opamps to passively monitor APORT buses without controlling the switches and creating bus conflicts. This can be done by setting APORTXMASTERDIS or APORTYMASTERDIS in the DACn_OPAx_CTRL register.

#### 24.3.4 Opamp Modes

The opamps can perform several different functions by configuring the internal signal routing between the opamps. The modes available are described in the following sections.

#### 24.3.4.1 General Opamp Mode

In this mode, the resistor ladder is isolated from the feedback path, and the input signal routing is defined by POSSEL and NEGSEL in VDACn_OPAx_MUX. The output signal routing is defined by the setting of VDACn_OPAx_OUT.

Table 24.4. General Opamp Mode Configuration

OPA Bitfields	OPA Configuration
OPAx POSSEL	POSPADx, APORT[1-4]X
OPAx NEGSEL	OPATAP, UG, NEGPADx, APORT[1-4]Y
OPAx RESINMUX	NEXTOUT, POSPADx, NEGPADx, VSS

#### 24.3.4.2 Voltage Follower Unity Gain

In this mode, the unity gain feedback path is selected for the negative input by setting the NEGSEL bit-field to UG in the VDACn_OPAx_MUX register as shown in Figure 24.4 Voltage Follower Unity Gain Overview on page 827. The positive input is selected by the POSSEL bit-field in VDACn_OPAx_MUX, and the output is configured by VDACn_OPAx_OUT register.

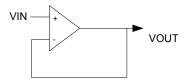

Figure 24.4. Voltage Follower Unity Gain Overview

Table 24.5. Voltage Follower Unity Gain Configuration

OPA Bitfields	OPA Configuration
OPAx POSSEL	OPATAP, NEXTOUT, POSPADx, APORT[1-4]X
OPAx NEGSEL	UG
OPAx RESINMUX	DISABLE

### 24.3.4.3 Inverting Input PGA

Figure 24.5 Inverting Input PGA Overview on page 827 shows the inverting input PGA configuration. In this mode, the negative input is connected to the resistor ladder by setting the NEGSEL bit-field to OPATAP in the VDACn_OPAx_MUX register. This setting provides a programmable gain on the negative input, which is set by the RESSEL bit-field in VDACn_OPAx_MUX. Signal ground for the positive input can come from off-chip by setting the POSSEL bit-field to PAD or APORT in VDACn_OPAx_MUX. In addition, the output is configured by VDACn_OPAx_OUT register.

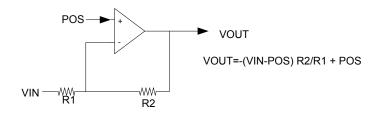

Figure 24.5. Inverting Input PGA Overview

Table 24.6. Inverting Input PGA Configuration

OPA Bitfields	OPA Configuration
OPAx POSSEL	POSPADx, APORT[1-4]X
OPAx NEGSEL	OPATAP
OPAx RESINMUX	NEXTOUT, NEGPADx, POSPADx

#### 24.3.4.4 Non-inverting PGA

Figure 24.6 Non-inverting PGA Overview on page 828 shows the non-inverting input configuration. In this mode, the negative input is connected to the resistor ladder by setting the NEGSEL bit-field to OPATAP in VDACn_OPAx_MUX. This setting provides a programmable gain on the negative input, which is set by the RESSEL bit-field in VDACn_OPAx_MUX. In addition, the RESINMUX bit-field must be set to VSS or NEGPAD in VDACn_OPAx_MUX. The positive input is selected by the POSSEL bit-field, and the output is configured by VDACn_OPAx_OUT register.

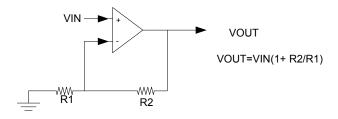

Figure 24.6. Non-inverting PGA Overview

Table 24.7. Non-inverting PGA Configuration

OPA Bitfields	OPA Configuration
OPAx POSSEL	NEXTOUT, POSPADx, APORT[1-4]X
OPAx NEGSEL	ОРАТАР
OPAx RESINMUX	VSS, NEGPAD

#### 24.3.4.5 Cascaded Inverting PGA

This mode enables the opamp signals to be internally configured to cascade two or more opamps in inverting mode as shown in Figure 24.7 Cascaded Inverting PGA Overview on page 829. In both cases, the positive input is connected to signal ground by setting the POSSEL bit-field to PAD or APORT in VDACn_OPAx_MUX. When cascaded, the negative input is connected to the resistor ladder by setting the NEGSEL bit-field to OPATAP in VDACn_OPAx_MUX. The input to the resistor ladder is configured by the RESINMUX bit-field in VDACn_OPAx_MUX.

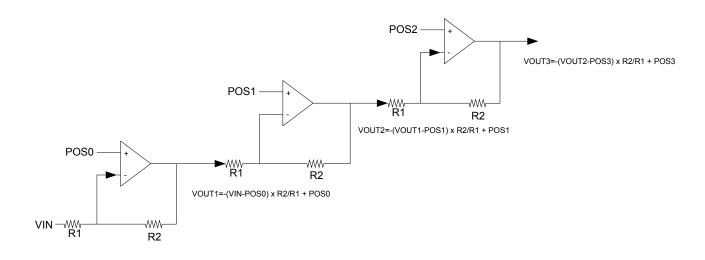

Figure 24.7. Cascaded Inverting PGA Overview

Table 24.8 Cascaded Inverting PGA Configuration on page 829 shows cascaded non-inverting PGA with OPA0,OPA1 and OPA2. The output from OPA0 is connected to OPA1 to create the second stage by setting the RESINMUX field to OPANEXT in VDACn OPA1 MUX. The last stage is created by setting the RESINMUX bit-field to OPANEXT in VDACn OPA2MUX.

Table 24.8. Cascaded Inverting PGA Configuration

OPA	OPA Bitfields	OPA Configuration				
OPA0	POSSEL	POSPAD0, APORT[1-4]X				
OPA0	NEGSEL	ОРАТАР				
OPA0	RESINMUX	NEGPAD0				
OPA1	POSSEL	POSPAD1, APORT[1-4]X				
OPA1	NEGSEL	ОРАТАР				
OPA1	RESINMUX	OPANEXT				
OPA2	POSSEL	POSPAD2,APORT[1-4]X				
OPA2	NEGSEL	OPATAP				
OPA2	RESINMUX	OPANEXT				

### 24.3.4.6 Cascaded Non-inverting PGA

This mode enables the opamp signals to be internally configured to cascade two or more opamps in non-inverting mode as shown in Figure 24.8 Cascaded Non-inverting PGA Overview on page 830. The negative input for all opamps will be connected to the resistor ladder by setting the NEGSEL bit-field to OPATAP. In addition the resistor ladder input must be set to VSS or NEGPADx by configuring the RESINMUX bit-field in VDACn_OPAx_MUX.

Figure 24.8. Cascaded Non-inverting PGA Overview

Table 24.9 Cascaded Non-inverting PGA Configuration on page 830 shows cascaded non-inverting PGA with OPA0,OPA1 and OPA2. When cascaded, the positive input on OPA0 is configured by the OPA0 POSSEL bit-field in VDACn_OPA0_MUX. The output from OPA0 is connected to OPA1 to create the second stage by setting the POSSEL field to OPANEXT in VDACn_OPA1_MUX. The last stage is created by setting the POSSEL bit-field to OPANEXT in VDACn_OPA2_MUX.

ОРА	OPA Bitfields	OPA Configuration

Table 24.9. Cascaded Non-inverting PGA Configuration

### 24.3.4.7 Two Opamp Differential Amplifier

This mode allows OPA0 and OPA1 or OPA1 and OPA2 to be internally connected to form a two opamp differential amplifier as shown in Figure 24.9 Two Op-amp Differential Amplifier Overview on page 831. When using OPA0 and OPA1, the positive input of OPA0 can be connected to any input by setting the POSSEL bit-field in VDACn_OPA0_MUX. The OPA0 feedback path must be configured for unity gain by setting the NEGSEL bit-field to UG in VDACn_OPA0_MUX. In addition, the OPA0 RESINMUX bit-field must be set to DISABLED. The OPA0 NEXTOUT output must be connected to OPA1 by setting the RESINMUX bit-field to OPANEXT in VDAC_n_OPA1_MUX. The positive input onof OPA1 is selected by the POSSELbit-field in VDACn_OPA1_MUX. The OPA1 output is configured by DACn_OPA1_OUT.

When using OPA1 and OPA2, the positive input of OPA1 can be connected to any input by setting the POSSEL bit-field in VDACn_OPA1_MUX. The OPA1 feedback path must be configured for unity gain by setting the NEGSEL bit-field to UG in VDACn_OPA1_MUX. In addition, the OPA1 RESINMUX bit-field must be set to DISABLED. The OPA1 NEXTOUT output must be connected to OPA2 by setting the RESINMUX bit-field to OPANEXT in VDACn_OPA2_MUX. The positive input of OPA2 is selected by the POSSEL bit-field in VDACn_OPA2_MUX. The OPA2 output is configured by DACn_OPA2_OUT.

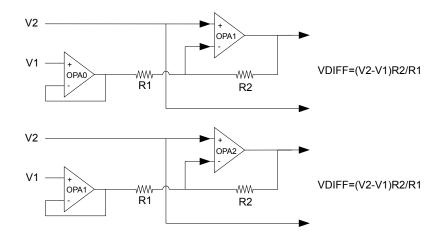

Figure 24.9. Two Op-amp Differential Amplifier Overview

Table 24.10. OPA0/OPA1 Differential Amplifier Configuration

OPA	OPA Bitfields	OPA Configuration			
OPA0	POSSEL	POSPAD0, APORT[1-4]X			
OPA0	NEGSEL	UG			
OPA0	RESINMUX	DISABLE			
OPA1	POSSEL	POSPAD1, APORT[1-4]X			
OPA1	NEGSEL	ОРАТАР			
OPA1	RESINMUX	OPANEXT			

Table 24.11. OPA1/OPA2 Differential Amplifier Configuration

#### 24.3.4.8 Three Opamp Differential Amplifier

This mode allows the three opamps to be internally configured to form a three opamp differential amplifier as shown in Figure 24.10 Three Op-amp Differential Amplifier Overview on page 832. For both OPA0 and OPA1, the positive input can be connected to any input by configuring the OPA0 POSSEL and OPA1 POSSEL bitfields in VDACn_OPA0_MUX and VDACn_OPA1_MUX, respectivley. The OPA0 and OPA1 feedback paths must be configured for unity gain by setting the OPA0 NEGSEL and OPA1 NEGSEL bitfields to UG in VDACn_OPA0_MUX and VDACn_OPA1_MUX respectivley. In addition the OPA0 RESINMUX and OPA1 RESINMUX bitfields must be set to DISABLED. The OPA1 output must be connected to OPA2 by setting RESINMUX to OPANEXT in VDACn_OPA2_MUX and the OPA2 POSSEL must be set to OPATAP. The OPA2 output is configured by the DACn_OPA2_OUT register.

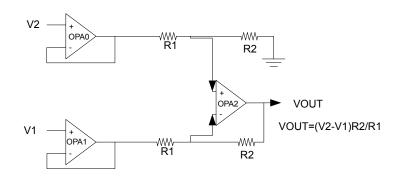

Figure 24.10. Three Op-amp Differential Amplifier Overview

The gain for the Three Opamp Differential Amplifier is determined by the combination of the gain settings of OPA0 and OPA2. Gain values of 1/3, 1 and 3, are available and programmed as shown in the table below.

Table 24.12. Three Opamp Differential Amplifier Gain Programming

Gain	OPA0 RESSEL	OPA2 RESSEL					
1/3	4	0					
1	1	1					
3	0	4					

Table 24.13. Three Opamp Differential Amplifier Configuration

OPA	OPA Bitfields	OPA Configuration				
OPA0	POSSEL	POSPAD0, APORT[1-4]X				
OPA0	NEGSEL	UG				
OPA0	RESINMUX	DISABLE				
OPA1	POSSEL	POSPAD1, APORT[1-4]X				
OPA1	NEGSEL	UG				
OPA1	RESINMUX	DISABLE				
OPA2	POSSEL	ОРАТАР				
OPA2	NEGSEL	ОРАТАР				
OPA2	RESINMUX	OPANEXT				

### 24.3.4.9 Instrumentation Amplifier

OPA0 and OPA1 can form a fully differential instrumentation amplifier by setting RESINMUX to CENTER for both opamps in VDACn_OPA0_MUX and VDACn_OPA1_MUX. Configuring RESINMUX to CENTER makes a connection between resistor ladder of the opamps as shown in Figure 24.11 Instrumentation Amplifier Overview on page 833.

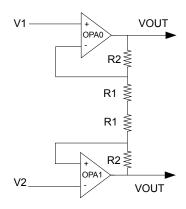

Figure 24.11. Instrumentation Amplifier Overview

#### 24.3.4.10 Common Reference

It is possible to configure all opamps to have a common reference by setting the RESINMUX to COMPAD in VDACn_OPAx_MUX. When RESINMUX of all opamps is set to COMPAD mode, the NEGPAD input of OPA0 is used.

#### 24.3.4.11 Dual Buffer ADC Driver

It is possible to use any two of the opamps to form a Dual Buffer ADC driver as shown in Figure 24.12 Dual Buffer ADC Driver Overview on page 833. Both opamps used must be configured in the same way. The positive input is configured by setting the 0PAx POSSEL to PAD, and the negative input is connected to the resistor ladder by setting NEGSEL to OPATAP in VDACn_OPAx_MUX. The output from the opamps can be configure to drive pins through the alternative output network or the APORT. The ADC can sample pins that the opamps are driving through the APORT.

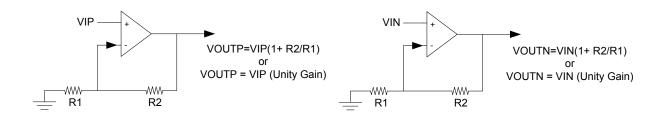

Figure 24.12. Dual Buffer ADC Driver Overview

Table 24.14. Dual Buffer ADC Driver Configuration

OPA	OPA Bitfields	OPA Configuration			
OPAx	POSSEL	POSPADx, APORT[1-4]X			
OPAx	NEGSEL	ОРАТАР			
OPAx	RESINMUX	VSS			

### 24.3.5 Opamp VDAC Combination

Since two of the OPAMPs are part of the VDAC, it is not possible to use both VDAC channels and all 3 OPAMPs at the same time. If both VDAC channels are used, OPA0 and OPA1 can not be used as stand-alone opamp. However, it is possible to use one of the VDAC channels in combination with OPA0 or OPA1. OPA1 is available when VDAC channel 0 is in use, and OPA0 is available when VDAC channel 1 is used.

### 24.4 Register Map

The register map of the opamp can be found in 23.4 Register Map in the VDAC chapter.

### 24.5 Register Description

The register description of the opamp can be found in 23.5 Register Description in the VDAC chapter.

### 25. ACMP - Analog Comparator

#### **Quick Facts**

#### What?

The Analog Comparator (ACMP) compares two analog signals and returns a digital value telling which is greater.

### Why?

Applications often do not need to know the exact value of an analog signal, only if it has passed a certain threshold. Often the voltage must be monitored continuously, which requires extremely low power consumption.

#### How?

Available down to Energy Mode 3 and using as little as 100 nA, the ACMP can wake up the system when input signals pass the threshold. The analog comparator can compare two analog signals or one analog signal and a highly configurable internal reference.

#### 25.1 Introduction

The Analog Comparator compares the voltage of two analog inputs and outputs a digital signal indicating which input voltage is higher. Inputs can either be from internal references or from external pins. Response time, and thereby the current consumption, can be configured by altering the current supply to the comparator.

#### 25.2 Features

- Up to 160 selectable external I/O inputs for both positive and negative inputs
  - Up to 48 I/O can be used as a dividable reference
- · 5 selectable internal inputs
  - · VDAC channel 0 voltage as a reference
  - VDAC channel 1 voltage as a reference
  - Dividable Internal 1.25 V bandgap reference voltage
  - · Dividable Internal 2.5 V bandgap reference voltage
  - Dividable V_{ACMPVDD} reference voltage
- · Voltage supply monitoring
- Low power mode for internal V DD and bandgap references
- · Selectable hysteresis
  - · 8 values
  - · Values can be positive or negative
  - · Dividable references have scale for both both output values, allowing for even larger hysteresis
- · Selectable response time
- · Asynchronous interrupt generation on selectable edges
  - · Rising edge
  - · Falling edge
  - · Both edges
- · Operational in EM0 Active down to EM3 Stop
- · Dedicated capacitive sense mode with up to 8 inputs
  - · Adjustable internal resistor
- · Configurable output when inactive
- · Comparator output direct on PRS
- · Comparator output on GPIO through alternate functionality
  - · Output inversion available

#### 25.3 Functional Description

An overview of the ACMP is shown in Figure 25.1 ACMP Overview on page 837.

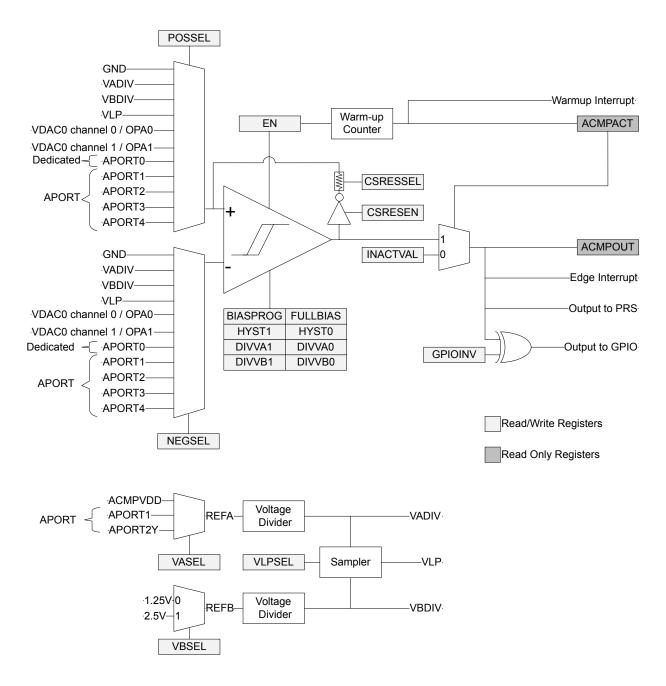

Figure 25.1. ACMP Overview

The comparator has two analog inputs: one positive and one negative. When the comparator is active, the output indicates which of the two input voltages is higher. When the voltage on the positive input is higher than the voltage on the negative input, the digital output is high and vice versa.

The output of the comparator can be read in the ACMPOUT bit in ACMPn_STATUS. It is possible to switch inputs while the comparator is enabled, but all other configuration should only be changed while the comparator is disabled.

### 25.3.1 Power Supply

The comparator power supply  $(V_{ACMPVDD})$  can be configured to be AVDD, DVDD, or IOVDD using the PWRSEL bitfield in ACMPn_CTRL. By default,  $V_{ACMPVDD}$  is set to AVDD.

#### 25.3.2 Warm-up Time

The analog comparator is enabled by setting the EN bit in ACMPn_CTRL. The comparator requires some time to stabilize after it is enabled. This time period is called the warm-up time. The warm-up period is self-timed and will complete within 5µs after EN is set.

During warm-up and when the comparator is disabled, the output level of the comparator is set to the value of the INACTVAL bit in ACMPn_CTRL. When the warm-up time is over, the ACMPACT bit in ACMPn_STATUS is set to 1 to indicate that the comparator is active.

An edge interrupt will be generated if the edge interrupt is enabled and the value set in INACTVAL differs from ACMPOUT when the comparator transitions from warm-up to active.

Software should wait until the warm-up period is over before entering EM2 or EM3, otherwise no comparator interrupts will be detected. EM1 can still be entered during warm-up. After the warm-up period is completed, interrupts will be detected in EM2 and EM3.

### 25.3.3 Response Time

There is a delay from when the input voltage changes polarity to when the output toggles. This delay is called the response time and can be altered by increasing or decreasing the bias current to the comparator through the BIASPROG and FULLBIAS fields in the ACMPn_CTRL register. The current and speed of the circuit increase as the values of FULLBIAS and BIASPROG are increased from their minimum setting of FULLBIAS=0 BIASPROG=0b000000 to the maximum setting FULLBIAS=1 BIASPROG=0b11111 (maximum). The setting of FULLBIAS has a greater affect on current and speed than the setting of BIASPROG. See the part data sheet for specific current and response times related to the setting of these fields.

If FULLBIAS is set, to avoid glitches the highest hysteresis level should be used.

#### 25.3.4 Hysteresis

When the hysteresis level is set to a non-zero value, the digital output will not toggle until the positive input voltage is at a voltage equal to the hysteresis level above or below the negative input voltage (see Figure 25.3 Hysteresis on page 839). This feature can be used to avoid continual comparator output changes due to noise when the positive and negative inputs are nearly equal by requiring the input difference to exceed the hysteresis threshold.

In the analog comparator, hysteresis can be configured to 8 different levels. Level 0 is no hysteresis. Hysteresis is configured through the HYST field in ACMPn_HYSTERESIS0 and ACMPn_HYSTERESIS1 registers. The hysteresis value can be positive or negative. The comparator will output a 1 if:

#### POSSEL - NEGSEL > HYST

There are two hysteresis registers, ACMPn_HYSTERESISO and ACMPn_HYSTERESIS1, as the ACMP supports asymmetric hysteresis. ACMPn_HYSTERESISO are the hysteresis values used when the comparator output is 0; ACMPn_HYSTERESIS1 are the values used when the comparator output is 1. The user must set both registers to the same values if symmetric hysteresis is desired.

Along with the HYST field, the ACMPn_HYSTERESIS0/1 registers include the DIVVA and DIVVB fields. This allows the user to implement even larger hysteresis when comparing against VADIV or VBDIV, as the reference voltage can vary with the comparator output, also.

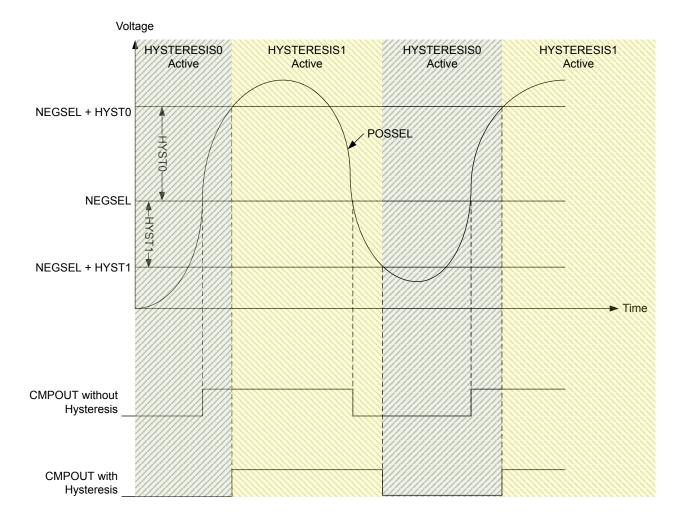

Figure 25.3. Hysteresis

#### 25.3.5 Input Pin Considerations

For external ACMP inputs routed through the APORT, the maximum supported analog input voltage will be limited to the  $MIN(V_{ACMPVDD}, IOVDD)$  (where  $V_{ACMPVDD}$  is selected by the PWRSEL bitfield in ACMPn_CTRL). Note that pins configured as ACMP inputs should disable OVT (by setting the corresponding GPIO_Px_OVTDIS bit) to reduce any potential distortion introduced by the OVT circuitry.

### 25.3.6 Input Selection

The POSSEL and NEGSEL fields in ACMPn_INPUTSEL control the input connections to the positive and negative inputs of the comparator. The user can select external GPIO pins on the chip, or select a number of internal chip voltages. Pins are selected by configuring channels on APORT buses. Not all selectable channels are available on a given device, as different devices within a family may not implement or bring out all of the I/O defined for that family. Refer to the data sheet for channel availability and pin mapping.

There are limitations on the POSSEL and NEGSEL connections that can be made. The user cannot select an X-bus for both POSSEL and NEGSEL simultaneously, nor a Y-bus for both POSSEL and NEGSEL simultaneously. The second limitation is that when using the feedback resistor only X-bus selections can be made for POSSEL. (The resistor only physically exists on the positive input of the comparator).

The user may also select from a number of internal voltages. VADIV and VBDIV are two dividable voltages. VADIV can be  $V_{ACMPVDD}$  divided, or the user can choose to select inputs from a number of APORT buses. VBDIV consists of two dividable band-gap references of either 1.25V or 2.5V. Each of these voltages have dividers in the ACMPn_HYSTERESISO/1 registers. The formula for the division of these voltages is:

 $VADIV = VA \cdot ((DIVVA+1)/64)$ 

Figure 25.3. VA Voltage Division

 $VBDIV = VB \cdot ((DIVVB+1)/64)$ 

Figure 25.4. VB Voltage Division

Either VADIV and VBDIV can also be used as an input to a lower power reference: VLP. Which of the two is used is configured via the VLPSEL field in ACMPn_INPUTSEL. If the user selects VLP as an input source, then VADIV or VBDIV cannot be used as the source for the other input.

Note: The VLP should not be selected as an input source when the external override interface is enabled.

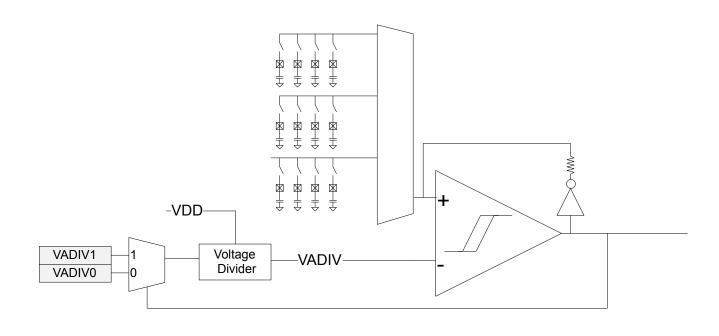

The POSSEL and NEGSEL fields also allow input from the on-chip VDAC channel 0 or VDAC channel 1.

ACMP can be configured to operate with a selected level of accuracy depending on the setting of ACCURACY in ACMPn_CTRL. The default is low-accuracy mode where ACMP operates with lower accuracy but consumes less current. When higher accuracy is needed the user can set ACCURACY=1 at the cost of higher current consumption.

#### 25.3.7 Capacitive Sense Mode

The analog comparator includes specialized hardware for capacitive sensing of passive push buttons. Such buttons are traces on the PCB laid out in a way that creates a parasitic capacitor between the button and the ground node. Because a human finger will have a small intrinsic capacitance to ground, the capacitance of the button will increase when the button is touched. The capacitance is measured by including the capacitor in a free-running RC oscillator (see Figure 25.5 Capacitive Sensing Setup on page 842). The frequency produced will decrease when the button is touched compared to when it is not touched. By measuring the output frequency with a timer (via the PRS), the change in capacitance can be detected.

The analog comparator contains a feedback loop including an optional internal resistor. This resistor is enabled by setting the CSRE-SEN bit in ACMPn_INPUTSEL. The resistance can be set to any of 8 values by configuring the CSRESSEL bits in ACMPn_INPUTSEL. The source for VADIV is set to V_{ACMPVDD} by setting field VASEL=0 in ACMPn_INPUTSEL. The oscillation rails are defined by the VADIV fields in registers ACMPn_HYSTERESISO/1. The user should select VADIV as the source for NEGSEL, and APORTXCHc for POSSEL in ACMPn_INPUTSEL. When enabled, the comparator output will oscillate between the rails defined by VADIV in ACMPn HYSTERESISO/1.

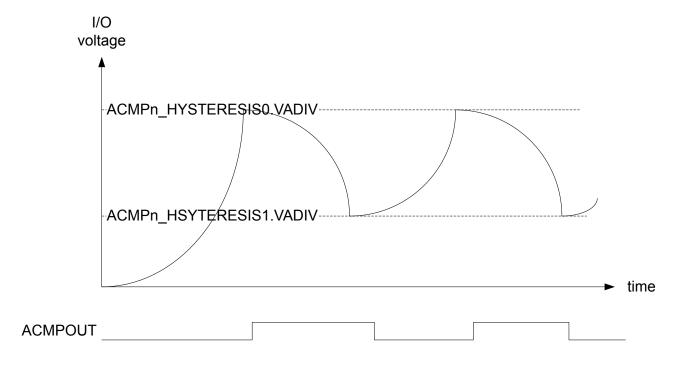

Figure 25.5. Capacitive Sensing Setup

#### 25.3.8 Interrupts and PRS Output

The analog comparator includes an edge triggered interrupt flag (EDGE in ACMPn_IF). If either IRISE and/or IFALL in ACMPn_CTRL is set, the EDGE interrupt flag will be set on rising and/or falling edge of the comparator output respectively. An interrupt request will be sent if the EDGE interrupt flag in ACMPn_IF is set and enabled through the EDGE bit in ACMPn_IEN. The edge interrupt can also be used to wake up the device from EM3 Stop-EM1 Sleep.

The analog comparator includes the interrupt flag WARMUP in ACMPn_IF which is set when a warm-up sequence has finished. An interrupt request will be sent if the WARMUP interrupt flag in ACMPn_IF is set and enabled through the WARMUP bit in ACMPn_IEN.

The analog comparator can also generate an interrupt if a bus conflict occurs. An interrupt request will be sent if the APORTCONFLICT interrupt flag in ACMPn IF is set and enabled through the APORTCONFLICT bit in ACMPn IEN.

The synchronized comparator output is also available as a PRS output signal.

#### 25.3.9 Output to GPIO

The output from the comparator and the capacitive sense output are available as alternate functions to the GPIO pins. Set the ACMP-PEN bit in ACMPn_ROUTE to enable the output to a pin and the LOCATION bits to select the output location. The GPIO-pin must also be set as output. The output to the GPIO can be inverted by setting the GPIOINV bit in ACMPn_CTRL.

#### 25.3.10 APORT Conflicts

The analog comparator connects to chip pins through APORT buses. It is possible that another APORT client is using a given APORT bus. To help debugging over-utilization of APORT resources the ACMP provides a number of status registers. The ACMPn_APORTREQ gives the user visibility into what APORT buses the ACMP is requesting given the setting of registers ACMPn_INPUTSEL and ACMPn_CTRL. ACMPn_APORTCONFLICT indicates if any of the selections are in conflict, internally or externally.

For example, if the user selects APORT1XCH0 for POSSEL and APORT3XCH1 for NEGSEL, then bits APORT1XCONFLICT and APORT3XCONFLICT would be 1 in register ACMPn_APORTCONFLICT, as it is illegal for POSSEL and NEGSEL to both select an X-bus simultaneously.

If the user wishes the ACMP to monitor the same pin as another APORT client within the system, the ACMP can be configured to not attempt to control the switches on an APORT bus via the fields APORTXMASTERDIS, APORTYMASTERDIS, and APORTVMASTERDIS and APORTYMASTERDIS control if the X or Y bus selected via POSSEL or NEGESEL is mastered or not. APORTVMASTERDIS controls if either the X or Y bus selection of VASEL is mastered or not. When bus mastering is disabled, it is the other APORT client that determines which pin is connected to the APORT bus.

### 25.3.11 Supply Voltage Monitoring

The ACMP can be used to monitor supply voltages. The ACMP can select which voltage it uses via PWRSEL in ACMPn_CTRL. This voltage can be selected for VADIV using VASEL=0 in ACMPn_INPUTSEL and divided to a voltage with the band-gap reference range using DIVVA in registers ACMPn_HYSTERESIS0/1. The band-gap reference voltage can also be scaled via DIVVB in registers ACMPn_HYSTERESIS0/1 to provide a voltage higher or lower than the scaled VA voltage for comparison.

#### 25.3.12 External Override Interface

The ACMP can be controlled by an external module, for instance LESENSE. In this mode, the external module will take control of the positive input mux control signal, which is normally controlled by ACMP_INPUTSEL_POSSEL. Only the APORTs are selectable for the positive input mux in this mode. Which APORT(s) used is configured in ACMP_EXTIFCTRL_APORTSEL. Additionally, the VLP should not be selected for the negative input mux in this mode.

Note: When the ACMP is controlled by the external interace, the ACMP warmup time may take up to 30 µs.

ACMP_EXTIFCTRL_APORTSEL also controls the base value for the positive input mux control signal. The external module will be able to add an offset to this base. The resulting mux configuration can be calculated using Figure 25.6 POSSEL in External Override Mode on page 844. The external module controls EXT_OFFSET, while EXT_BASE is controlled by ACMP. See register description of ACMP_EXTIFCTRL_APORTSEL to see values of EXT_BASE.

POSSEL = EXT_BASE + EXT_OFFSET

### Figure 25.6. POSSEL in External Override Mode

**Note:** If only one APORT in a pair is used, the external module needs to be programmed to only use the channels that the ACMP has control of.

The external module is also able to override DIVVA and DIVVB in ACMP_HYSTERESIS0/HYSTERESIS1. This needs to be enabled in the external module. If the external module does not override DIVVA/DIVVB, the configuration in ACMP_HYSTERESIS0/HYSTERESIS1 will be used.

To enable the external override interface these steps must be performed:

- Configure the parts of the ACMP that will not be overridden, i.e. everything except ACMP_INPUTSEL_POSSEL and possibly ACMP_HYSTERESIS0/HYSTERESIS1. Make sure ACMP_CTRL_EN is set.
- Configure and enable the external override interface in ACMP_EXTIFCTRL.
- · Check for APORT conflicts in ACMP APORTCONFLICT.
- Wait for ACMP STATUS EXTIFACT to go high, indicating that the interface is ready to use.

#### 25.4 Register Map

The offset register address is relative to the registers base address.

Offset	Name	Туре	Description

15	ACCURACY	0	RW	ACMP Accuracy Mode							
	Select between low and high accuracy mode of the comparator. Note, high frequency changes can cause the ACMP performance to degrade. For such uses, such as quickly scanning through multiple channels or setting the ACMP to oscillate for capacitive sense, this bit should be set to 1.										
	Value	Mode		Description							
	0	LOW		ACMP operates in low-accuracy mode but consumes less current.							
	1	HIGH		ACMP operates in high-accuracy mode but consumes more current.							
14:12	PWRSEL	0x0	RW	Power Select							
	Selects the power source for the ACMP(ACMPVDD). NOTE, this field should only be changed when the block is disabled (EN=0).										
	Value	Mode		Description							
	0	AVDD		AVDD supply							
	1	DVDD		DVDD supply							
	2	IOVDD0		IOVDD/IOVDD0 supply							
	4	IOVDD1		IOVDD1 supply (if part has two I/O voltages)							
11	Reserved	To ensure contions	mpatibility v	with future devices, always write bits to 0. More information in 1.2 Conven-							
10	APORTVMASTER- DIS	0	RW	APORT Bus Master Disable for Bus Selected By VASEL							
	devices to monitor the the determination is a selection of channel f	Determines if the ACMP will request the X or Y APORT bus selected by VASEL. This bit allows multiple APORT connected devices to monitor the same APORT bus simultaneously by allowing the ACMP to not master the selected bus. When 1, the determination is expected to be from another peripheral, and the ACMP only passively looks at the bus. When 1, the selection of channel for a selected bus is ignored (the bus is not), and is whatever selection the external device mastering the bus has configured for the APORT bus.									
	Value			Description							
	0			Bus mastering enabled							
	1			Bus mastering disabled							
9	APORTYMASTER- DIS	0	RW	APORT Bus Y Master Disable							
	connected devices to When 1, the determin 1, the selection of cha	Determines if the ACMP will request the APORT Y bus selected by POSSEL or NEGSEL. This bit allows multiple APORT connected devices to monitor the same APORT bus simultaneously by allowing the ACMP to not master the selected bus. When 1, the determination is expected to be from another peripheral, and the ACMP only passively looks at the bus. When 1, the selection of channel for a selected bus is ignored (the bus is not), and is whatever selection the external device mastering the bus has configured for the APORT bus.

# 26. ADC - Analog to Digital Converter

### **Quick Facts**

## What?

The ADC is used to convert analog signals into a digital representation and features low-power, autonomous operation.

# Why?

In many applications there is a need to measure analog signals and record them in a digital representation, without exhausting the energy source.

### How?

A low power ADC samples up to 32 input channels in a programmable sequence. With the help of PRS and DMA, the ADC can operate without CPU intervention in EM2 Deep Sleep and EM3 Stop, minimizing the number of powered up resources. The ADC can further be duty-cycled to reduce the energy consumption.

## 26.1 Introduction

The ADC uses a Successive Approximation Register (SAR) architecture, with a resolution of up to 12 bits at up to one million samples per second (1 Msps). The integrated input multiplexer can select from external I/Os and several internal signals.

#### 26.2 Features

- Programmable resolution (6/8/12-bit)
  - 13 conversion clock cycles for a 12-bit conversion
  - Maximum 1 Msps @ 12-bit
  - Maximum 1.6 Msps @ 6-bit
- · Configurable acquisition time
- · Externally controllable conversion start time using PRS in TIMED mode
- Integrated prescaler for conversion clock generation
  - · Selectable clock division factor from 1 to 128
- · Wide conversion clock range: 32 kHz to 16 MHz
- · Can be run during EM2 Deep Sleep and EM3 Stop, waking up the system upon various enabled interrupts
- Can be run during EM2 Deep Sleep and EM3 Stop with DMA enabled to pull data from the FIFOs without waking up the system
- Supports up to 144 external input channels and several internal inputs
  - Includes temperature sensor and random number generator function
- · Left or right adjusted results
  - · Results in 2's complement representation
  - · Differential results sign extended to 32-bits results
- · Programmable scan sequence
  - · Up to 32 configurable samples in scan sequence
  - · Mask to select which pins are included in the sequence
  - · Triggered by software or PRS input
  - · One shot or repetitive mode
  - · Oversampling available
  - · Four deep FIFO to store conversion data along with channel ID and option to overwrite old data when full
  - · Programmable watermark (DVL) to generate SCAN interrupt
  - · Supports overflow and underflow interrupt generation
  - · Supports window compare function
  - · Conversion tailgating support for predictable periodic scans
- · Programmable single channel conversion
  - · Triggered by software or PRS input
  - · Can be interleaved between two scan sequences
  - · One shot or repetitive mode
  - · Oversampling available
  - · Four deep FIFO to store conversion data with option to overwrite old data when full
  - programmable watermark (DVL) to generate SINGLE interrupt
  - · Supports overflow and underflow interrupt generation
  - · Supports window compare function
- · Hardware oversampling support
  - · 1st order accumulate and dump filter
  - From 2 to 4096 oversampling ratio (OSR)
  - · Results in 16-bit representation
  - · Enabled individually for scan sequence and single channel mode
  - · Common OSR select
- Programmable and preset input full scale (peak-to-peak) range (VFS) with selectable reference sources
  - VFS=1.25 V using internal VBGR reference
  - · VFS=2.5 V using internal VBGR reference
  - · VFS=AVDD with AVDD as reference source
  - VFS=5 V with internal VBGR reference
  - · Single ended external reference
  - · Differential external reference
  - VFS=2xAVDD with AVDD as reference source
  - · User-programmable dividers for flexible VFS options from internal, external or supply voltage reference sources

- · Support for offset and gain calibration
- · Interrupt generation and/or DMA request when
  - · Programmable number of converted data available in the single FIFO (also generates DMA request)
  - · Programmable number of converted data available in the scan FIFO (also generates DMA request)
  - · Single FIFO overflow or underflow
  - · Scan FIFO overflow or underflow
  - · Latest Single conversion tripped compare logic
  - · Latest Scan conversion tripped compare logic
  - · Analog over-voltage interrupt
  - Programming Error interrupt due to APORT Bus Request conflict or NEGSEL programming error

# 26.3 Functional Description

An overview of the ADC is shown in Figure 26.1 ADC Overview on page 869.

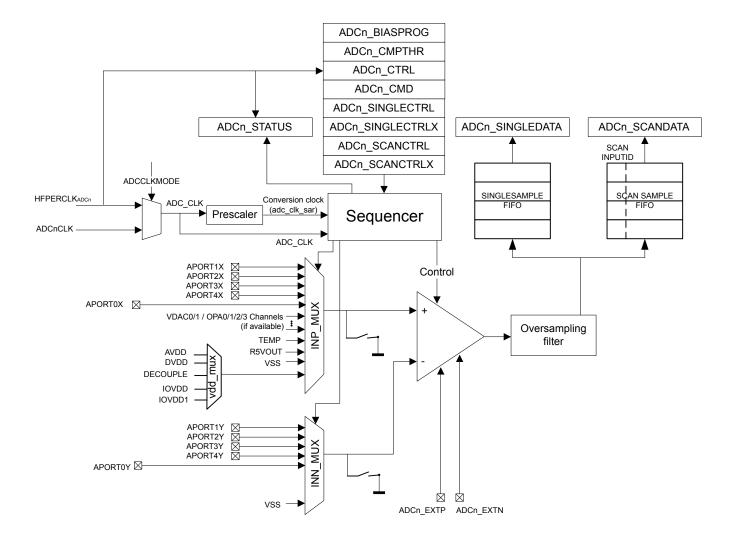

Figure 26.1. ADC Overview

## 26.3.1 Clock Selection

The ADC logic is partitioned into two clock domains: HFPERCLK and ADC_CLK. The HFPERCLK domain contains the register interface logic, APORT request logic and portions of FIFO read logic. The HFPERCLK is the default clock for the ADC peripheral. The rest of the ADC is clocked by the ADC CLK domain. The ADC CLK is chosen by ADCCLKMODE bit in the ADCn CTRL register.

The ADC_CLK is the main clock for the ADC engine. If the ADCCLKMODE is set to SYNC, the ADC_CLK is equal to the HFPERCLK and the ADC operates in synchronous mode. If the ADCCLKMODE is set to ASYNC, the ADC_CLK is ASYNCCLK and the ADC operates in asynchronous mode. This distinction is important to understand as there are additional system restrictions and benefits to running the ADC in asynchronous mode detailed in 26.3.15 ASYNC ADC_CLK Usage Restrictions and Benefits.

Note: Whenever ADC is being used in asynchronous mode, then HFPERCLK must be at least 1.5 times higher than the ADC_CLK.

The ADC has an internal clock prescaler, controlled by PRESC bits in ADCn_CTRL, which can divide the ADC_CLK by any factor between 1 and 128 to generate the conversion clock (adc_clk_sar) for the ADC. This adc_clk_sar is also used to generate acquisition timing. Note that the maximum clock frequency for adc_clk_sar is 16 MHz. The ADC warmup time is determined by ADC_CLK and not by adc_clk_sar.

ASYNCCLK is a clock source from the CMU which is considered asynchronous to HFPERCLK. The CMU_ADCCTRL register can be programmed to request and use ASYNCCLK. It has multiple choices for its source, including AUXHFRCO, HFXO and HFSRCCLK, and can optionally be inverted. If the chosen source for ASYNCCLK is not active at the time of request, the CMU enables the source oscillator upon receiving the request, and shuts down the oscillator when the ADC stops requesting the clock. Consult the CMU chapter for details of how to program the clock sources for the ASYNCCLK and oscillator start-up time details.

Software may choose a clock request generation scheme by programming the ASYNCCLKEN and WARMMODE of the ADCn_CTRL register. If the ASYNCCLKEN is set to ASNEEDED with WARMMODE set to NORMAL, the ADC requests ASYNCCLK only when a conversion trigger is activated. The ASYNCCLK request is withdrawn after the conversion is complete. All other options keep the ASYNCCLK request "ON" until software programs these fields otherwise or changes the ADCCLKMODE to SYNC.

For EM2 Deep Sleep or EM3 Stop operation of the ADC, the ADC_CLK must be configured for AUXHFRCO as this is the only available option during EM2 Deep Sleep or EM3 Stop. The ADC_CLK source should not be changed as the system enters or exits various energy modes, otherwise measurement inaccuracies will result.

## 26.3.2 Conversions

A conversion consists of two phases: acquisition and approximation. The input is sampled in the acquisition phase before it is converted to digital representation during the approximation phase. The acquisition time can be configured independently for scan sequence and single channel conversions (see 26.3.3 ADC Modes) by setting AT in ADCn_SINGLECTRL/ADCn_SCANCTRL. The acquisition times can be set to 1, 2, 3 or any integer power of 2 from 4 to 256 adc clk sar cycles.

**Note:** For high impedance sources the acquisition time should be adjusted to allow enough time for the internal sample capacitor to fully charge. The minimum acquisition time for sampling at 1 Msps and typical input loading is 187.5 ns.

The ADC uses one adc clk sar cycle per output bit in the approximation phase plus 1 extra adc clk sar cycle.

Where T_{acq} is the acquisition time set by the AT bit field, N is the resolution (in bits), and OVSRSEL is the oversampling ratio according to the OVSRSEL field in ADCn_CTRL when oversampling is enabled (see 26.3.10.6 Oversampling).

Figure 26.2. ADC Total Conversion Time Per Output

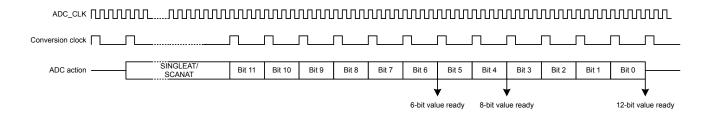

Figure 26.3. ADC Conversion Timing

### 26.3.3 ADC Modes

The ADC contains two programmable modes: single channel mode and scan mode. Both modes have separate configuration registers and a four-deep FIFO for conversion results. Both modes may be set up to run only once per trigger or to automatically repeat after each operation. The scan mode has priority over the single channel mode. However by default, if scan sequence is running, a triggered single channel conversion will be interleaved between two scan samples.

# 26.3.3.1 Single Channel Mode

Single channel mode can be used to convert a single channel either once per trigger or repetitively. The configuration of single channel mode is done using the ADCn_SINGLECTRL and ADCn_SINGLECTRLX registers and the result FIFO can be read through the ADCn_SINGLEDATA register. The DVL field of the ADCn_SINGLECTRLX controls the FIFO watermark crossing which sets the SINGLEDV bit in ADCn_STATUS high and is cleared when the data is read and the number of unread data samples falls below the DVL threshold. The user can choose to throw out new samples or overwrite the old samples when the FIFO becomes full by programming the FIFOOFACT field of the ADCn_SINGLECTRLX register. Single channel results can also be read through ADCn_SINGLEDATAP without popping the FIFO, returning its latest element. The DIFF field in ADCn_SINGLECTRL selects whether differential or single ended inputs are used and POSSEL and NEGSEL selects the input signal(s). The CMPEN bit in the ADCn_SINGLECTRL register enables the window compare function, and the latest converted data is compared against values programmed into the ADGT and ADLT fields of the ADCn_CMPTHR register and generates SINGLECMP interrupts if enabled. The window compare function allows for compare triggering both within (if ADGT less than ADLT) or out of (if ADGT greater than ADLT) window.

## 26.3.3.2 Scan Mode

Scan mode is used to perform conversions across multiple channels, sweeping a set of selected inputs in a sequence. The configuration of scan mode is done in the ADCn_SCANCTRL and ADCn_SCANCTRLX registers. It has similar controls and data read mechanisms to single channel mode. There are two key differences between single channel mode and scan mode: the input sequence is programmed differently, and it has additional information in the result to indicate the channel on which the conversion was acquired. 26.3.7 Input Selection explains how the input sequence is chosen. When the scan sequence is triggered, the ADC samples all inputs that are included in the mask (ADCn_SCANMASK), starting at the lowest pin number. DIFF in ADCn_SCANCTRL selects whether single ended or differential inputs are used. The FIFO data is tagged with SCANINPUTID and can be read along with the scan data using ADCn_SCANDATAX register. The ADCn_SCANDATAXP can be used to read the latest valid entry from the scan FIFO without popping it. There is also a ADCn_SCANDATA register that contains results without the SCANINPUTID appended.

**Note:** If using scan mode with ADCn_SCANCTRL_REP = 1 and ADCn_SCANCTRLX_REPDELAY = NODELAY, the last channel in the scan will report a SCANINPUTID of 0. Using ADCn_SCANCTRLX_REPDELAY with any value other than NODELAY will report the correct SCANINPUTID.

# 26.3.4 Warm-up Time

After power-on, the ADC requires some time for internal bias currents and references to settle prior to starting a conversion. This time period is called the warm-up time. Warm-up timing is performed by hardware. Software must program the number of ADC_CLK cycles required to count at least 1  $\mu$ s in the TIMEBASE field of the ADCn_CTRL register. TIMEBASE only affects the timing of the warm-up sequence and is not dependent on adc_clk_sar. When enabling the ADC or changing references between samples, the ADC is automatically warmed up for 5  $\mu$ s (5 times the period indicated by TIMEBASE).

Normally, the ADC will be warmed up only when samples are requested and is shut off when there are no more samples waiting. However, if lower latency is needed, configuring the WARMUPMODE field in ADCn_CTRL allows the ADC and/or reference to stay warm between samples, reducing the warm-up time or eliminating it altogether. Figure 26.4 ADC Analog Power Consumption With Different WARMUPMODE Settings on page 873 shows the effects on analog power consumption in scenarios using different WARMUPMODE settings.

The user can program which reference should be kept warm in the CHCONREFWARMIDLE bitfield in the ADCn_CTRL register. By default the scan mode reference is kept warm. The user can also choose to keep the single channel mode reference warm or to keep the last used reference warm. If the default setting is kept (scan mode reference is to be kept warm) and if the single-mode reference setting is different than scan-mode, then single mode conversions will first warmup its reference for 5 µs before a conversion can begin.

Various warmup modes are described here:

- NORMAL: This is the lowest power option for general-purpose use and low sampling rates (below 35 ksps). The ADC and references are shut off when there are no samples waiting. The ADC does not consume any power when it is shut down. A 5 µs warmup time will be initiated prior to every conversion. Figure a in Figure 26.4 ADC Analog Power Consumption With Different WARMUP-MODE Settings on page 873 shows this mode.
- KEEPINSTANDBY: This mode is suitable for infrequent sampling of lower impedance inputs, and is the lowest power option for sampling rates between about 35 and 125 ksps. It may also be useful for lower sampling rates where latency is important. The reference selected for scan mode is kept warm, but the ADC is powered down. The ADC will initiate a 1 µs warmup period before a conversion begins. Because the reference is kept warm, the ADC will consume a small amount of standby current when it is not converting. Figure b in Figure 26.4 ADC Analog Power Consumption With Different WARMUPMODE Settings on page 873 shows this mode.
- KEEPINSLOWACC: This mode is useful for high-impedance inputs which are sampled infrequently. It is similar to KEEPINSTAND-BY, but continuously tracks the input, keeping the input multiplexer connected to the APORT bus. This mode consumes little more power than KEEPINSTANDBY mode (about 2 µA extra) when a conversion is not in progress. This allows the user to avoid programming long acquisition time that would otherwise be necessary for high-impedance inputs when ADC wakes up to full power mode, thereby reducing the total current consumption per conversion.
- KEEPADCWARM: This mode provides the lowest latency and allows for maximum sampling rates. The ADC and reference circuitry
  remain powered on even when conversions are not in progress. Figure c in Figure 26.4 ADC Analog Power Consumption With Different WARMUPMODE Settings on page 873 shows this mode. This mode consumes the most power, but as soon as a trigger
  event occurs, the acquisition and conversion begin with no warm-up time. Note that if KEEPADCWARM mode is set and HFXO is
  selected as the ADC clock source, the HFXO will remain on in EM2.

When KEEPADCWARM is chosen, ADC is termed as being in continuous operation. When any other warmup mode is chosen, ADC is termed to be in duty-cycled operation.

When entering EM2 Deep Sleep or EM3 Stop, if the ADC is not going to be used, it should be returned to an idle state and WARMUP-MODE in ADCn_CTRL written to 0. Refer to 26.3.17 ADC Programming Model for more information on placing the ADC in an idle state. If the ADC is going to be used in these low energy modes, the user can use any of the WARMUPMODE settings, but should be mindful of the power consumption that comes along with the different mode settings. For EM2 Deep Sleep or EM3 Stop operation, the ADC clock source must be configured to use AUXHFRCO.

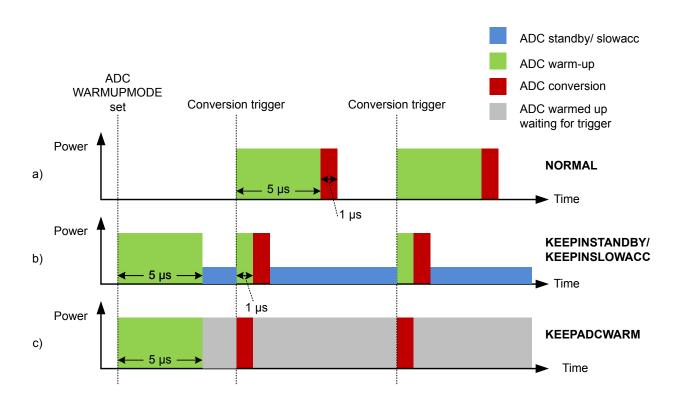

Figure 26.4. ADC Analog Power Consumption With Different WARMUPMODE Settings

Note: When using any warm-up mode other than NORMAL, always switch back to the NORMAL mode before switching to another warm-up mode.

## 26.3.5 Power Supply

The ADC block power (V_{ADC}) is derived from the VDDX_ANA supply rail. VDDX_ANA can be selected from the AVDD or DVDD supply pins using the EMU_PWRCTRL_ANASW bit field.

# 26.3.6 Input Pin Considerations

For external ADC inputs routed through the APORT, the maximum supported analog input voltage will be limited to the MIN( $V_{ADC}$ , IOVDD) (where  $V_{ADC}$  is VDDX_ANA, as described in 26.3.5 Power Supply). Note that pins configured as ADC inputs should disable OVT (by setting the corresponding GPIO_Px_OVTDIS bit) to reduce any potential distortion introduced by the OVT circuitry.

ADC external reference inputs are not routed through the APORT, and the maximum supported analog input voltage for an external reference will also be limited to the  $MIN(V_{ADC}, IOVDD)$ .

## 26.3.7 Input Selection

The ADC samples and converts the analog voltage differential at its positive and negative voltage inputs. The input multiplexers of the ADC can connect these inputs to one of several internal nodes (e.g., temperature sensor) or to external signals via analog ports (APORT0, APORT1, APORT2, APORT3 or APORT4).

The analog ports APORT1, APORT2, APORT3, and APORT4 connect to external pins via analog buses (BUSAX, BUSAY, BUSAY, etc.) which are shared among other analog peripherals on the device. APORT1 through APORT4 are each 32 channels wide with connections to two sub-buses: a 16-channel X bus and a 16-channel Y bus. In the ADC module, all X buses connect to the INP_MUX and all Y buses connect to the INN_MUX as shown in Figure 26.5 APORT Connection to the ADC on page 874. Connections to the X and Y sub-buses alternate channels on the APORT. On APORT1 and APORT3, even-numbered channels connect to the X bus, and odd-numbered channels connect to the Y bus. On APORT2 and APORT4, even-numbered channels connect to the Y bus and odd-numbered channels connect to the X bus. The APORT to BUS mappings may vary from device to device, Refer to the APORT Client Map in the device data sheet for exact mappings.

Unlike APORT1 through APORT4, APORT0 is not a shared resource. It consists of a 16-channel X bus and a 16-channel Y bus, each with dedicated I/O pin connections. Note that APORT0 is not available on all device families.

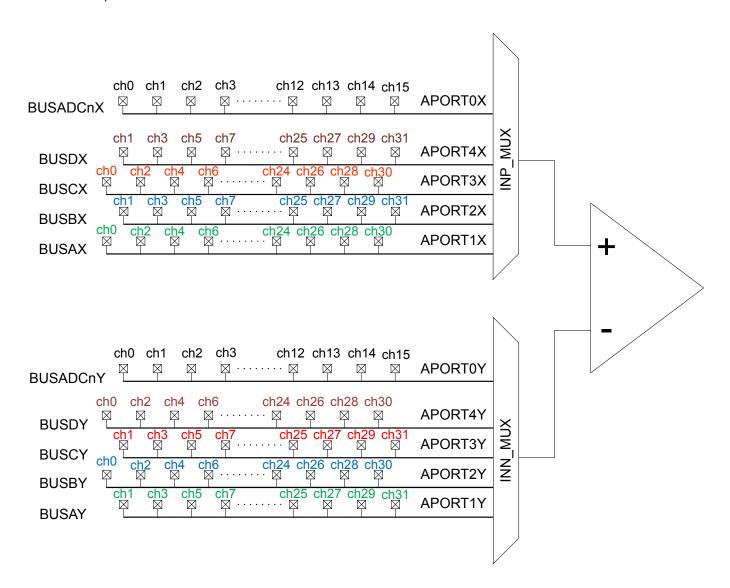

Figure 26.5. APORT Connection to the ADC

For differential measurements, one input must be chosen from an X bus and the other from a Y bus. Choosing both inputs from an X bus or both from a Y bus will generate a PROGERR interrupt (if enabled) of NEGSELCONF type. The PROGERR type can be checked in the ADCn_STATUS register.

The mapping and availability for external I/O connections to ADC0 inputs is shown in device data sheet.

Multiple peripherals may request the same shared system bus (BUSAX, BUSAY, BUSBX, etc.). When this happens, a conflict status is generated and that bus is kept floating. If this happens with the ADC, the PROGERR field in ADCn_STATUS is set to BUSCONF, and an interrupt may be generated (if enabled). When connecting dedicated I/Os through APORTO, all inputs are available to APORTOX and APORTOY and no bus conflict is possible. Refer to 26.3.7.3 APORT Conflicts for more information on identifying and resolving bus conflicts.

Note: The internal inputs can only be sampled in single channel, single-ended mode. NEGSEL should be fixed to VSS for these conversions

# 26.3.7.1 Configuring ADC Inputs in Single Channel Mode

In single channel mode, the ADCn_SINGLECTRL register provides the POSSEL and NEGSEL selection for positive and negative channel selection of the ADC. The APORT Client Map provides external pin to internal bus channel mapping enumeration for a particular device. Software can also choose internal nodes for POSSEL.

For single-ended conversions on external (APORT-connected) signals, POSSEL and NEGSEL are fully configurable. However, when performing conversions on internal signals, NEGSEL must be set to VSS. This NEGSEL reconfigurability feature in single-ended mode may not be available in all devices. If compatibility with devices that do not support this feature is desired, NEGSEL should be set to VSS for all single channel single-ended conversions.

Note that in both the POSSEL and NEGSEL fields, it is possible to choose inputs from both X and Y buses, even though X channels are physically connected to the positive mux (INP_MUX) and Y channels are physically connected to the negative mux (INN_MUX). For single-ended operation (DIFF = 0), if the positive input is chosen from a Y channel the ADC performs a negative single ended conversion and automatically inverts the result at the end, producing a positive result. For differential conversions (DIFF = 1), if a Y channel is chosen for the positive input and an X channel is chosen for the negative input, the ADC result will be inverted to produce the correct polarity.

Refer to device-specific data sheet for specific pin connection options. Note that the same I/O pin may appear in multiple locations.

# 26.3.7.2 Configuring ADC Inputs in Scan Mode

In scan mode, the ADC can sample and convert up to 32 external channels on each conversion trigger. Internal channels are not available in scan mode. The ADC's scanner logic automatically changes the input mux settings between conversions, eliminating the need for firmware intervention.

The ADC scanner logic is controlled by a set of 32 logical channels called SCANINPUTIDs. The 32 SCANINPUTIDs are arranged in four groups of 8 channels each. Each channel group can point to a predefined series of 8 sequential channels on any of the available APORTs. The ADCn_SCANINPUTSEL register is used to configure which group of physical APORT channels each of the SCANINPUTID channel groups map to. For example, selecting APORT1CH16TOCH23 in the INPUT7TO0SEL field selects APORT1CH16 for SCANINPUTID0, APORT1CH17 for SCANINPUTID1, APORT1CH18 for SCANINPUTID2, and so on.

The four SCANINPUTID groups are fully independent and may be selected from any APORT in any combination. It is possible also to repeat the same selection in multiple groups. For example, the user may select APORT2CH0TOCH7 for all four of the SCANINPUTID groups.

In many cases, the user application will not require all 32 channels of the scanner to be converted. Each of the scanner channels may be individually enabled according to the needs of the system. The ADCn_SCANMASK register is used to enable and disable individual SCANINPUTIDs. The bits in the ADCnSCANMASK register correspond one-to-one with the SCANINPUTID channel numbers. During a scan operation, the ADC scanner logic will convert only the enabled SCANINPUTIDs, in order from lowest to highest.

In single-ended mode, all conversions performed by the ADC will be relative to VSS. For any enabled SCANINPUTID, the selected APORT channel will be connected to the ADC with the opposite ADC input terminal connected to VSS. Note that the channel groups selected in ADCn_SCANINPUTSEL point to a block of 8 channels on an APORT, which includes both X and Y channels. Depending on the channels enabled by ADCn_SCANMASK, the ADC may perform conversions on the X or the Y bus associated with that APORT.

Figure 26.6 ADC Single-ended Scan Mode Example on page 876 shows an example of a single-ended scan configuration. In this example, ADCn_SCANINPUTSEL has been configured to place APORT1CH16TO23 in the first, third, and fourth channel groups. APORT4CH8TO15 has been placed in the second channel group. ADCn_SCANMASK selects six of these channels for inclusion in the scan. When an ADC scan is initiated with this configuration, the ADC begins at SCANINPUTID0 and converts each enabled channel in turn. This scan configuration results in a set of six single-ended ADC conversions: PF0, PF3, PA5, PA5, PF7, and PF4.

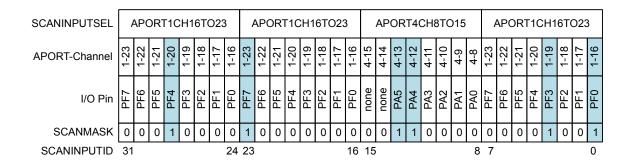

Figure 26.6. ADC Single-ended Scan Mode Example

In differential mode, the default operation of the ADC scanner is to perform a differential measurement between the selected APORT channel and the next channel on that APORT. For example, if the enabled SCANINPUTID points to APORT1CH6, the ADC will perform a differential conversion between APORT1CH6 and APORT1CH7.

There are two exceptions to this rule, listed in order of precedence:

- 1. When converting SCANINPUTID15, the differential conversion will be performed between the channel selected by SCANINPUTID15 and the channel selected by SCANINPUTID8.
- 2. When APORTnCH31 is the selected input, the differential conversion will be performed between APORTnCH31 and APORTnCH0.

Figure 26.7 ADC Differential Scan Mode Example on page 877 shows an example of a differential scan configuration. In this example, ADCn_SCANINPUTSEL has been configured to place APORT1CH16TO23 in the first, third, and fourth channel groups. APORT4CH8TO15 has been placed in the second channel group. ADCn_SCANMASK selects three channels pairs for inclusion in the scan. When an ADC scan is initiated with this configuration, the ADC begins at SCANINPUTID0 and converts each enabled channel in turn. This scan configuration results in a set of three differential ADC conversions: PF0-PF1, PF2-PF3, and PA4-PA5.

Figure 26.7. ADC Differential Scan Mode Example

In certain applications it may be desirable to perform differential conversions on several channels against a common voltage. The ADCn_SCANNEGSEL register allows eight of the SCANINPUTIDs to re-map the negative terminal of a differential conversion to a common channel. In the first ADCn_SCANINPUTSEL group, the negative input for SCANINPUT 0, 2, 4, and 6 may be re-mapped to any of the odd-numbered channels in that group (SCANINPUT 1, 3, 5, or 7). Likewise, in the second ADCn_SCANINPUTSEL group, the negative input for SCANINPUT 9, 11, 13, and 15 may be re-mapped to any of the even-numbered channels in that group (SCANINPUT 8, 10, 12, or 14).

Figure 26.8 ADC Differential Scan Mode Re-mapping Negative Input Selections on page 877 shows the effects of the ADCn_SCAN-NEGSEL register on the re-mappable inputs. The left side of the figure shows the default channel mapping, and the right side of the figure shows how ADCn_SCANNEGSEL can be programmed to map the same negative input on up to four channels.

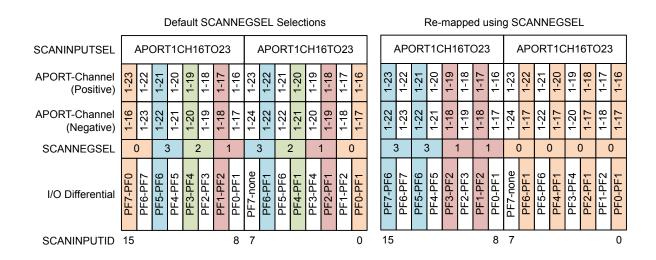

Figure 26.8. ADC Differential Scan Mode Re-mapping Negative Input Selections

## 26.3.7.3 APORT Conflicts

The ADC shares common analog buses connected to its APORTs (1-4) with other analog peripherals (see device-specific data sheet). As the ADC performs single or scan conversions, it requests the shared buses and sends selections for the control switches to connect the desired I/O pins. If another analog peripheral requests the same shared bus at the same time, there will be a collision and none of the peripherals will be granted control of that bus.

To help debug over-utilization of APORT resources, the ADC hardware provides status information in local registers. The ADCn_APORTREQ register gives the user visibility into which APORT(s) the ADC is requesting given the setting of the input selection registers. ADCn_APORTCONFLICT reports any conflicts that occur. If PROGERR in ADCn_IEN is set, any conflict generates an interrupt. The PROGERR field in the ADCn_STATUS register indicates whether the programming error happened as a result of an APORT bus conflict (BUSCONF) or from a negative-input selection conflict (NEGSELCONF). If the PROGERR interrupt occurred due to a negative selection conflict, then the interrupt can be cleared by software only after correcting the conflict. If a software clear is attempted without correcting the configuration, the interrupt will be cleared for one clock cycle but then it will trigger again as the invalid configuration still persists.

**Note:** The ADC requests shared bus connections as soon as that bus is selected in the input select registers, even if the ADC is not performing any conversions. This means that by using the APORT request, the ADC will acquire the associated shared analog bus, preventing other peripherals from using it. The bus will be released only when the input select registers are changed.

It is possible for the ADC to passively monitor shared bus signals without controlling the switches and creating bus conflicts. This can be done by setting the ADCn_APORTMASTERDIS register. When ADCn_APORTMASTERDIS is used, channel selection defers to the peripheral acting as the bus master for that shared bus, and no bus conflict will occur. The ADC will connect its input to the shared bus, but the specific channel will be controlled by the peripheral designated as the bus master.

# 26.3.8 Reference Selection and Input Range Definition

The full scale voltage (VFS) of the ADC is defined as the full input range, from the lowest possible input voltage to the highest. For single-ended conversions, the input range on the selected positive input is from 0 to VFS. For differential conversions, the input to the converter is the difference between the positive and negative input selections. This can range from -VFS/2 to +VFS/2.

VFS for the converter is determined by a combination of the selected voltage reference (VREF) and programmable divider circuits on the ADC input and voltage reference paths. Users have full control over the VREF and divider selections, offering a very flexible and wide selection of VFS values. In most applications however, it is not necessary to adjust VFS beyond a set of common pre-defined choices. For the simplest VFS configuration, refer to 26.3.8.1 Basic Full-Scale Voltage Configuration. If the application requires a VFS configuration not available in the pre-defined choices, 26.3.8.2 Advanced Full-Scale Voltage Configuration covers additional configuration options.

## 26.3.8.1 Basic Full-Scale Voltage Configuration

Basic configuration of the VFS (full scale voltage) for the converter is done by programming the REF bitfield in ADCn_SINGLECTRL (for single channel mode) or ADCn_SCANCTRL (for scan mode) to any of the pre-defined options. The list of available pre-defined VFS options is:

- VFS = 1.25 V using internal VBGR as the reference source
- VFS = 2.5 V using internal VBGR as the reference source
- VFS = AVDD using AVDD as the reference source (AVDD ≤ 3.6 V)
- VFS = 5 V using internal VBGR as the reference source
- VFS = ADCn EXTP external pin as a single-ended reference source (1.2 V 3.6 V)
- VFS = ADCn EXTP ADCn EXTN external pins as a differential reference source. (1.2 V 3.6 V difference)
- VFS = 2 x AVDD using AVDD as the reference source (AVDD ≤ 3.6 V)

The maximum and minimum input voltage which the ADC can recognize at any external pin is limited to the minimum of the  $V_{ADC}$  and IOVDD supply voltages (where  $V_{ADC}$  is VDDX_ANA, as described in 26.3.5 Power Supply). If VFS is configured to be larger than the supply range, the full ADC range will not be available. For example, with a 3.3 V supply and VFS configured to 5 V, the input voltage for single-ended conversions will be limited to 0 to 3.3 V, though the effective VFS is still 5 V.

The ADC uses a chip-level bias circuit to provide bias current for its operation. For highest accuracy when using a VBGR-derived internal bandgap reference source, GPBIASACC in ADCn_BIASPROG should be cleared to 0 (HIGHACC). This will allow the ADC to enable high-accuracy mode from the bias circuitry during conversions. When AVDD or an external pin reference option is used, software may set GPBIASACC in ADCn_BIASPROG to 1 (LOWACC) to conserve energy. Note that VDAC and dc-dc usage may also switch the chip-level bias to high- accuracy mode (even if GPBIASACC is set to LOWACC), potentially impacting ADC results. For example, if ADC is doing a conversion with GPBIASACC set to LOWACC and VDAC also starts a conversion using the internal low noise reference, then the chip-level bias circuit will be automatically switched to high-accuracy mode (potentially corrupting results of the on-going ADC conversion). Similarly, dc-dc startup automatically switches the chip-level bias circuit to high-accuracy mode for a short time, i.e., if dc-dc startup happens when ADC is doing a conversion (with GPBIASACC set to LOWACC), ADC results may get corrupted. DC-DC startup automatically switches the bias circuit to high-accuracy mode for 25 µs. It is during this time that ADC conversions with the GPBIASACC set to LOWACC should be avoided.

If the pre-defined VFS options do not suit the particular application, refer to 26.3.8.2 Advanced Full-Scale Voltage Configuration for more advanced VFS options.

## 26.3.8.2 Advanced Full-Scale Voltage Configuration

For most applications, the pre-defined VFS options described in 26.3.8.1 Basic Full-Scale Voltage Configuration are suitable. Advanced VFS configurations are also possible by programming the REF bitfield in ADCn_SINGLECTRL or ADCn_SCANCTRL to the CONF option. Programming the REF bitfield to CONF allows the user to select the specific VREF source and adjust the programmable input and reference divider options directly.

The general procedure for programming an advanced VFS configuration is as follows:

- 1. Select the voltage reference source using VREFSEL.
- 2. Configure VREFATTFIX and VREFATT so that the reference voltage at the ADC is between 0.7 and 1.05 V.
- 3. Configure VINATT to achieve the desired full-scale voltage.

The VREFSEL field in ADCn_SINGLECTRLX or ADCn_SCANCTRLX selects the voltage reference source. The ADC can choose from the following voltage reference (VREF) sources:

- VBGR: An internal 0.83 V bandgap reference voltage. This is the most precise internal reference source available.
- VDDXWATT: An attenuated version of the AVDD supply voltage. The attenuation factor is determined by the VREFATTFIX and/or VREFATT bit fields.
- VREFPWATT: An external reference source applied to the ADCn_EXTP pin, and attenuated by the attenuation factor (determined by the VREFATTFIX and/or VREFATT bit fields). This is the appropriate choice for external reference inputs greater than 1.05 V.
- VREFP: An external reference source applied to the ADCn_EXTP pin, without any attenuation. This is the appropriate choice for external reference inputs between 0.7 V and 1.05 V.
- VENTROPY: A very low internal reference voltage (approx. 0.1 V). This option is intended to be used only with the ADC inputs tied internally to VSS, for generating random noise at the ADC output.
- VREFPNWATT: A differential version of VREFPWATT, with the reference source applied to the ADCn_EXTP and ADCn_EXTN pins and attenuated. This is the appropriate choice where a differential reference of greater than 1.05 V is required.
- VREFPN: A differential version of VREFP, with the reference source applied to the ADCn_EXTP and ADCn_EXTN pins and no attenuation. This is the appropriate choice where a differential reference of between 0.7 V and 1.05 V is required.
- VBGRLOW: An internal 0.78 V bandgap reference voltage.

The ADC reference voltage should be attenuated to a lower voltage when using AVDD or the external reference source. A simple method for a wide range of reference sources is to set VREFATTFIX to 1. The VREF attenuation factor (ATT_{VREF}) can then be selected between 1/3 (when VREFATT is greater than 0), and 1/4 (when VREFATT is equal to 0). For reference sources between 1.2 V and 3.6 V, ATT_{VREF} = 1/3 is the best choice. ATT_{VREF} = 1/4 can be used with references from 1.6 V to 3.8 V, with slight performance degradation.

Finer granularity on  $ATT_{VREF}$  is possible as well, by clearing VREFATTFIX to 0, and setting the VREFATT field. For optimal performance with VREFATTFIX = 0, the attenuated ADC reference input should be limited to between 0.7 V and 1.05 V. When VREFATTFIX is cleared to 0,  $ATT_{VREF}$  is set according to the equation:

ATT_{VREF} = (VREFATT + 6) / 24 for VREFATT < 13, and (VREFATT - 3) / 12 for VREFATT ≥ 13

Figure 26.9. ATT_{VREF}: VREF Attenuation Factor

The ADC input also includes a programmable attenuator. The VIN attenuator is used to widen the available input range of the ADC beyond the reference source. The VIN attenuation factor (ATT_{VIN}) is determined by the VINATT field according to the equation:

ATT_{VIN} = VINATT / 12 for VINATT ≥ 3 (settings 0, 1, and 2 are not allowable values for VINATT)

Figure 26.10. ATT_{VIN}: VIN Attenuation Factor

VFS can be calculated by the formula given below for any given VREF source, VREF attenuation, and VIN attenuation:

VFS = 2 · VREF · ATT_{VREF} / ATT_{VIN}

VREF is selected in the VREFSEL bitfield, and

ATT_{VREF} is the VREF attenuation factor, determined by VREFATT or VREFATTFIX

ATT_{VIN} is the VIN attenuation factor, determined by VINATT

Figure 26.11. VFS: Full-Scale Input Range

The maximum and minimum input voltage which the ADC can recognize at any external pin is limited to the minimum of the  $V_{ADC}$  and IOVDD supply voltages (where  $V_{ADC}$  is VDDX_ANA, as described in 26.3.5 Power Supply). If VFS is configured to be larger than the supply range, the full ADC range will not be available. For example, with a 3.3 V supply and VFS configured to 5 V, the input voltage for single-ended conversions will be limited to 0 to 3.3 V, though the effective VFS is still 5 V.

The ADC uses a chip-level bias circuit to provide bias current for its operation. For highest accuracy when using a VBGR-derived internal bandgap reference source, GPBIASACC in ADCn_BIASPROG should be cleared to 0 (HIGHACC). This will allow the ADC to enable high-accuracy mode from the bias circuitry during conversions. When AVDD or an external pin reference option is used, software may set GPBIASACC in ADCn_BIASPROG to 1 (LOWACC) to conserve energy. Note that VDAC and dc-dc usage may also switch the chip-level bias to high- accuracy mode (even if GPBIASACC is set to LOWACC), potentially impacting ADC results. For example, if ADC is doing a conversion with GPBIASACC set to LOWACC and VDAC also starts a conversion using the internal low noise reference, then the chip-level bias circuit will be automatically switched to high-accuracy mode (potentially corrupting results of the on-going ADC conversion). Similarly, dc-dc startup automatically switches the chip-level bias circuit to high-accuracy mode for a short time, i.e., if dc-dc startup happens when ADC is doing a conversion (with GPBIASACC set to LOWACC), ADC results may get corrupted. DC-DC startup automatically switches the bias circuit to high-accuracy mode for 25 µs. It is during this time that ADC conversions with the GPBIASACC set to LOWACC should be avoided.

The combination of VREF,  $ATT_{VREF}$  and  $ATT_{VIN}$  can produce a wide range of full-scale voltage options for the converter. Table 26.1 Advanced VFS Configuration: VREF = AVDD on page 881 shows some example VFS configurations using AVDD as a reference source.

Table 26.1. Advanced VFS Configuration: VREF = AVDD

AVDD Voltage	VREF Attenuation Set- tings	Reference Voltage at ADC	VIN Attenuation Set- tings	VFS
1.85 V	VREFATTFIX = 0	0.925 V	VINATT = 12	1.85 V
	VREFATT = 6		ATT _{VIN} = 1	(+/-0.925 V differential)
	ATT _{VREF} = 1/2			
3.0 V	VREFATTFIX = 0	1.0 V	VINATT = 8	3.0 V
	VREFATT = 2		ATT _{VIN} = 2/3	(+/-1.5 V differential)
	ATT _{VREF} = 1/3			
3.0 V	VREFATTFIX = 0	1.0 V	VINATT = 4	6.0 V
	VREFATT = 2		ATT _{VIN} = 1/3	(+/-3.0 V differential)
	ATT _{VREF} = 1/3			
3.6 V	VREFATTFIX = 1	0.9 V	VINATT = 6	3.6 V
	VREFATT = 0		ATT _{VIN} = 1/2	(+/-1.8 V differential)
	ATT _{VREF} = 1/4			

## 26.3.9 Programming of Bias Current

The ADC uses a chip-level bias generator to provide bias current for its operation. The ADC's internal bias can be scaled by ADCBIA-SPROG field of the ADCn_BIASPROG register. At lower conversion speeds, the ADCBIASPROG can be used to lower active power. Some commonly used settings are given in the ADCBIASPROG register description. For proper operation, the ADC conversion speed must be scaled accordingly. The scale factor is calculated as:

Bias scale factor = (1- ADCBIASPROG[2:0]/8) / (1+3·ADCBIASPROG[3])

## Figure 26.12. Bias Scale Factor

The bias programming register also includes the VFAULTCLR bit field. If VREFOF interrupt is enabled and it is triggered, then the user needs to set this bit in the ISR before clearing the interrupt flag. This bit then needs to be reset after the interrupt flag is cleared in order to enable the VREFOV flag to trigger on the next VREFOV condition.

The bias current settings should only be changed while the ADC is disabled (i.e. in NORMAL warm-up mode and no conversion in progress).

### 26.3.10 Feature Set

The following sections explain different ADC features.

# 26.3.10.1 Conversion Tailgating

Scan conversions have priority over single channel conversions. This means that if scan and single triggers are received simultaneously, or even if the scan is received later when ADC is being warmed up for performing a single conversion, the scan conversion will have priority and will be done before the single conversion. However, a scan trigger will not interrupt in the middle of a single conversion, i.e., if the single conversion is in the acquisition or approximation phase, then the scan will have to wait for the single conversion to complete. If a scan sequence is triggered by a timer on a periodic basis, single channel conversion that started just before a scan trigger can delay the start of the scan sequence, thus causing jitter in sample rate. To solve this, conversion tailgating can be chosen by setting TAILGATE in ADCn_CTRL. When this bit is set, any triggered single channels will wait for the next scan sequence to finish before activating (see Figure 26.13 ADC Conversion Tailgating on page 882). The single channel will then follow immediately after the scan sequence. In this way, the scan sequence will always start immediately when triggered, provided that the period between the scan triggers is big enough to allow the single sample conversion that was triggered to finish before the next scan trigger arrives. Note that if tailgating is set and a single channel conversion is triggered, it will indefinitely wait for a scan conversion before starting the single channel conversion.

Figure 26.13. ADC Conversion Tailgating

## 26.3.10.2 Repetitive Mode

Both single channel and scan mode can be run as a one shot conversion or in repetitive mode. The REP bitfield in ADCn_SIN-GLECTRL/ADCn_SCANCTRL registers can be used to activate the repetitive mode for single and scan respectively. In order to achieve the maximum sampling rate of 1 Msps, repetitive mode should be used.

It is also possible to have a programmable delay between these repetitive conversions. The REPDELAY bitfield in the ADCn SIN-GLECTRLX and ADCn SCANCTRLX registers can be used to set the delay between two repeated conversions in single channel and scan mode respectively. For single channel mode when a single conversion in repetitive mode ends, the user programmed REPDELAY is inserted and then the next single conversion is re triggered after the delay period is over. For scan mode the REPDELAY is inserted after the entire scan sequence ends. Once the delay period is over, scan mode is internally re-triggered. Note that when the ADC is in SYNC mode and REPDELAY is set to generate a delay, it takes an additional 5 HFPERCLK cycles after the trigger before the next conversion begins. If REPDELAY is set to NODELAY, the next conversion begins immediately, without any delay or additional HFPERCLKs. The 26.3.10.1 Conversion Tailgating explains how the single channel and scan mode conversions can push each other out of phase. Conversion tailgating can be chosen in repetitive mode as well in order to ensure that the scan sequence will always start immediately when triggered, provided the scan REPDELAY chosen is big enough for the single conversion to finish. The status flags SINGLEACT and SCANACT stay high throughout the repeat mode, i.e., even during the delay period. The flags show that the conversions are either active or pending. Whether the ADC turns off or stays warmed up between these repeated conversions depends on the WARMUPMODE chosen in the ADCn CTRL register. When using single channel mode with repeat mode and REPDELAY enabled, then once the ADC has started operation (i.e., singleact status flag has gone high) then no new single conversion triggers (software START/ PRS triggers) should be sent to the ADC until the ADC has stopped converting (i.e., singleact status flag has gone low). The same applies to scan sequence conversions.

# 26.3.10.3 Conversion Trigger

The conversion modes can be activated by writing a 1 to the SINGLESTART or SCANSTART bit in the ADCn_CMD register. The conversions can be stopped by writing a 1 to the SINGLESTOP or SCANSTOP bit in the ADCn_CMD register. A START command will have priority over a STOP command. When the ADC is stopped in the middle of a conversion, the result buffer is cleared (the FIFO contents for any prior conversions are still intact). Every time a STOP command is issued, the user should wait for the corresponding status flag (SINGLEACT/SCANACT) to go low and then either read all the data in the FIFO or send the corresponding FIFOCLEAR command. The SINGLEACT and SCANACT bits in ADCn_STATUS are set high when the modes are actively converting or have pending conversions.

It is also possible to trigger conversions from PRS signals. The PRS is treated as an asynchronous trigger. Setting PRSEN in ADCn_SINGLECTRL/ADCn_SCANCTRL enables triggering from PRS input. Which PRS channel to listen to is defined by PRSSEL in ADCn_SINGLECTRLX/ADCn_SCANCTRLX. When PRS trigger is selected, it is still possible to trigger a conversion from software. Refer to the PRS chapter for more information on how to set up the PRS channels. When the conversions are triggered using the ADCn_CMD register, then the SINGLEACT and SCANACT bits in the ADCn_STATUS are set as soon as the START command is written to the register. When the conversion is triggered using PRS, it takes some cycles from the time PRS trigger is received until the SINGLEACT and SCANACT bits are set due to the synchronization requirement. If SINGLEACT is already high then sending a new START command or a new PRS trigger for a single conversion will not have any impact as ADC already has a single conversion ongoing or a single conversion pending (single conversion can be pending if ADC is busy running a scan sequence). The same rules apply for SCANACT and SCAN START and PRS triggers. When software issues a SINGLE/SCAN STOP command, it must wait until SINGLEACT/ SCANACT flag goes low before issuing a new START.

The PRS may trigger the ADC in two possible ways, configured by PRSMODE in ADCn_SINGLECTRLX/ADCn_SCANCTRLX. In PULSED mode, a PRS pulse triggers the ADC to start the ADC_CLK (if not already enabled), warm up (if not already warm), start the acquisition period, and perform the conversion. This is identical to issuing a START command from software. In this mode, the input sampling finishes at the end of the acquisition period (AT).

If the ADC_CLK and the source of the trigger (START command or PRS pulse) are not synchronous, the frequency of the input sampling (FS), will experience a  $1_{1/2}$  to  $2_{1/2}$  ADC_CLK cycle jitter due to synchronization requirements.

To precisely control the sample frequency, the PRSMODE can be set to TIMED mode. In this mode, a long PRS pulse is expected to trigger the ADC and its negative edge directly finishes input sampling and starts the approximation phase, giving precise sampling frequency management. The restriction is that the PRS pulse has to be long enough to start the ADC_CLK (if not already enabled), and finish the acquisition period based on the AT field in ADCn_SINGLECTRL/ADCn_SCANCTRL. The PRS pulse needs to be high when AT event finishes. If it is not high when AT finishes, then it is ignored and input sampling finishes after AT event has ended (a two cycle latency is added to the conversion in this scenario). In this case, the ADC sets the PRSTIMEDERR interrupt flag.

If the PRS pulse is too long (e.g., FS = 32kHz), the analog ADC start can be delayed to save power. The CONVSTARTDELAY along with its EN in the ADCn_SINGLECTRLX or ADCn_SCANCTRLx can be programmed to implement a 0 to 8 microseconds delay. The microsecond tick is counted by TIMEBASE with ADC_CLK similar to warmup case. This saves power as the ADC is not enabled until the last possible microsecond before the fall edge of the PRS arrives to open the sampling switch and to start the approximation phase. Figure 26.14 ADC PRS Timed Mode with ASNEEDED ADC_CLK Request on page 884) shows PRS Timed mode triggering with CONVSTARTDELAY and ASNEEDED ADC_CLK request. See that power is saved by both delaying the ADC EN and by requesting the ADC_CLK only during ADC operation. This is especially useful in saving power when running the ADC in EM2 Deep Sleep or EM3 Stop power mode with low sampling frequency.

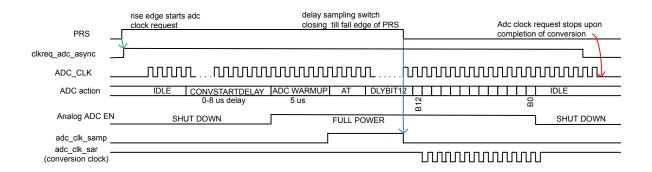

Figure 26.14. ADC PRS Timed Mode with ASNEEDED ADC CLK Request

When a PRS pulse is received, if the ADC_CLK is not running (ASNEEDED mode), then the ADC requests the clock by setting clkreq_adc_async high. If the chosen clock source (HFXO/ HFSRCCLK/ AUXHFRCO) is already running, then it takes 5 ADC_CLK cycles after the clock request is asserted for the ADC_CLK to start. HFXO and HFSRCCLK (if chosen as ADC clock source) need to be already running before ADC sends out the clock request. If AUXHFRCO is chosen as the ADC clock source, and it is not already

running, then the CMU automatically turns it on when the ADC sends a clock request. In such a case, it takes (7 ADC_CLK cycles + the oscillator startup time) for the ADC CLK to start. The oscillator startup time can be found in the device data sheet.

When triggering repeat mode using PRS and then stopping the triggered mode using STOP command, ensure that the PRS pulse used to generate the repeat mode has gone low by the time the STOP command is issued. If the PRS pulse continues to stay high after ADC has stopped the ongoing conversion, then it will be picked as a new trigger to start a new conversion.

#### Note:

- The conversion settings should not be changed while the ADC is running. Doing so may lead to unpredictable behavior.
- The adc_clk_sar phase is always reset by a conversion trigger as long as a conversion is not in progress. This gives predictable latency from the time of the trigger to the time the conversion starts, regardless of when in the trigger occurs.
- Software and LESENSE should not trigger conversions if PRS Timed mode is selected and PRSEN is set to 1 in the ADCn_SIN-GLECTRL/ADCn_SCANCTRL register.
- If the PRS Timed mode is being used, the acquisition time (AT) must be set greater than 0.

Scan conversions can be triggered using LESENSE as well. LESENSE only triggers one input conversion at a time (not the whole sequence of 32 possible inputs). The input to be converted using LESENSE must be configured by the user in the ADCn_SCANINPUT-SEL register before triggering the conversion, i.e., one of the 32 inputs chosen in the ADCn_SCANINPUTSEL register must be the one that is to be converted using LESENSE. The ADCn_SCANMASK is not used for LESENSE triggered conversions. Instead, the user can select which input should be converted through LESENSE inside the LESENSE settings (LESENSE_CHX). The results of LESENSE triggered conversions are not loaded in the FIFO/ DATA registers but are instead available in the LESENSE register. Similarly, the SCAN interrupt flag is not set on completion of a LESENSE triggered conversion (because that flag is set only when the data is written to the Scan FIFO). When there is a LESENSE triggered conversion going on or pending, the SCANACT status flag is set. The SCAN-PEND interrupt flag is set when a software/PRS triggered scan goes pending because a LESENSE triggered scan is running (software/PRS triggered scan will start after the currently running LESENSE scan conversion completes). Similarly, SCANEXTPEND interrupt flag is set when the LESENSE triggered scan conversion goes pending because a software/PRS triggered scan is running. LESENSE triggered conversions can be stopped at any time using the SCANSTOP command in the ADCn_CMD register. Note that the LESENSE triggered conversion cannot trigger the Scan repeat mode.

The DBGHALT bit-field in the ADCn_CTRL register can be used to choose the ADC behavior in debug mode. If this bit is set to 1, then in debug mode ADC completes the current conversions and then halts. This means that all conversion triggers that were received before the debug halt occurred will be serviced before the ADC halts. All conversion triggers received after the ADC was halted, will be serviced when the debug mode is not halted any more. If the repetitive mode is running (in repetitive mode ADC keeps doing conversions until the user sends a software STOP) and a debug mode halt occurs, then the ADC will gracefully complete the current on-going conversion and then halt. The repetitive mode conversions will restart as soon as the debug mode is not halted any more.

# 26.3.10.4 Output Results

ADC output results are presented in 2's complement form and the format for single ended and differential conversions are given in Table 26.2 ADC Single Ended Conversion on page 886 and Table 26.3 ADC Differential Conversion on page 886, respectively. If differential mode is selected, the results are sign extended up to 32-bits (shown in Table 26.5 ADC Results Representation on page 887).

Table 26.2. ADC Single Ended Conversion

Input Voltage	Output	Results
input voltage	Binary	Hex value
4095/4096 · VFS	11111111111	FFF
0.5 · VFS	10000000000	800
1/4096 · VFS	00000000001	001
0	00000000000	000

Innut	Output	Results
Input	Binary	Hex value
2047/4096 · VFS	01111111111	7FF
0.25 · VFS	01000000000	400
1/4096 · VFS	00000000001	001
0	00000000000	000
-1/4096 · VFS	11111111111	FFF
-0.25 · VFS	11000000000	C00
-0.5 · VFS	10000000000	800

# **26.3.10.5 Resolution**

The ADC performs 12-bit conversions by default. However, if full 12-bit resolution is not needed, it is possible to speed up the conversion by selecting a lower resolution (6 or 8 bits). For more information on the accuracy of the ADC, the reader is referred to the electrical characteristics section for the device.

# 26.3.10.6 Oversampling

To achieve higher accuracy, hardware oversampling can be enabled individually for each mode (Set RES in ADCn_SINGLECTRL/ADCn_SCANCTRL to 0x3). The oversampling rate (OVSRSEL in ADCn_CTRL) can be set to any integer power of 2 from 2 to 4096 and the configuration is shared between the scan and single channel mode (OVSRSEL field in ADCn_CTRL).

With oversampling, each input is sampled at 12-bits of resolution a number of times (given by OVSRSEL), and the results are filtered by a first order accumulate and dump filter to form the end result. The data presented in the ADCn_SINGLEDATA and ADCn_SCANDATA registers are the direct contents of the accumulation register (sum of samples). However, if the oversampling ratio is set higher than 16x, the accumulated results are shifted to fit the MSB in bit 15 as shown in Table 26.4 Oversampling Result Shifting and Resolution on page 887.

Table 26.4. Oversampling Result Shifting and Resolution

Oversampling setting	# right shifts	Result Resolution # bits
2x	0	13
4x	0	14
8x	0	15
16x	0	16
32x	1	16
64x	2	16
128x	3	16
256x	4	16
512x	5	16
1024x	6	16
2048x	7	16
4096x	8	16

# 26.3.10.7 Adjustment

By default, all results are right adjusted, with the LSB of the result in bit position 0 (zero). In differential mode the signed bit is extended up to bit 31, but in single ended mode the bits above the result are read as 0. By setting ADJ in ADCn_SINGLECTRL/ADCn_SCANCTRL, the results are left adjusted as shown in Table 26.5 ADC Results Representation on page 887. When left adjusted, the MSB is always placed on bit 15 and sign extended to bit 31. All bits below the conversion result are read as 0 (zero).

Table 26.5. ADC Results Representation

Adjustment	Resolution								Bits									
		31 16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	12	11 11	11	11	11	11	11	10	9	8	7	6	5	4	3	2	1	0
Right	8	7 7	7	7	7	7	7	7	7	7	7	6	5	4	3	2	1	0
Right	6	5 5	5	5	5	5	5	5	5	5	5	5	5	4	3	2	1	0

	ovs	15 15	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

### 26.3.10.8 Channel Connection

The inputs are connected to the analog ADC at the beginning of the acquisition phase and are disconnected at the end of the acquisition phase. The time when the APORT switches are closed (for the next input to be converted) can be controlled by the CHCONMODE bitfield in the ADCn_CTRL register. By default, this field is set to the MAXSETTLE option. For MAXSETTLE, APORT switches are closed on the next input as soon as the acquisition phase for the current conversion is complete. This means that the APORT switches are closed approximately 12 adc_clk_sar cycles (assuming 12 bit resolution) before the acquisition phase of the current conversion starts, giving APORT switches maximum time to settle. The time for which APORT switches should be closed before the acquisition phase starts, should be the same for all inputs in order to get consistent results. This means that if the ADC is warmed up with CHCON-REFWARMIDLE set to 0 (scan reference warmed up and the APORT switches for the first scan channel closed) and a single trigger comes in, the single conversion will have to wait 12 adc_clk_sar cycles before it can start (even if single is using the same reference as scan). In this case, it might be more suitable to switch to the MAXRESP option in the CHCONMODE bitfield. In MAXRESP, the APORT switches for the upcoming conversion are closed just before the acquisition phase starts. This gives less settling time to the APORT switches but removes the extra waiting time before a conversion can start (which could be the case with MAXSETTLE as discussed above).

## 26.3.10.9 Temperature Measurement

The ADC includes an internal temperature sensor. This sensor is measured during production test and the temperature readout from the ADC at production temperature, ADC0CAL3_TEMPREAD1V25, is given in the Device Information (DI) page. The production temperature, CAL_TEMP, is also given in this page. The temperature sensor slope, V_TS_SLOPE (mV/degree Celsius), for the sensor is found in the data sheet for the device. Using the 1.25 V VFS option and 12-bit resolution, the temperature can be calculated according to the following formula (VFS in the formula is 1250 mV):

T_{CELSIUS} = CAL_TEMP - (ADC0CAL3_TEMPREAD1V25 - ADC_result) · VFS / (4096· V_TS_SLOPE)

Figure 26.15. ADC Temperature Measurement

### Note:

- The minimum acquisition time for the temperature reference is found in the electrical characteristics for the device. If using the 1.25 V reference, extra acquisition time is required. In this case the AT field of ADCn_SINGLECTRL or ADCn_SCANCTRL should be set to a value of 9 or higher.
- For the most accurate temperature sensor results, GPBIASACC in ADCn_BIASPROG should be set to 0 to keep the bias in HIGH-ACC mode.
- If the device has more than one ADC, all ADCs may not be equipped with the temperature sensor. See the device data sheet.

# 26.3.10.10 ADC as a Random Number Generator

The ADC can be used as a random number generator. This is done by:

- 1. Choose the REF in the ADCn_SINGLECTRL as CONF, setting the VREFSEL in the ADCn_SINGLECTRLX as VENTROPY and VINATT in the same register to its maximum value of 15.
- 2. Set DIFF to 1 and RES to 0 in the ADCn SINGLECTRL register.
- 3. Trigger a single channel conversion and then read ADCn_SINGLEDATA register when the conversion finishes.

The LSB[2:0] of each sample will be a random number. In this mode, the POSSEL or NEGSEL in ADCn_SINGLECTRL can be connected to VSS or any other noisy input.

## 26.3.11 Interrupts, PRS Output

The single and scan modes have separate SINGLE and SCAN interrupt flags indicating whether corresponding FIFO contains DVL # of valid conversion data. Corresponding interrupt enable bit has to be set in ADCn_IEN in order to generate interrupts. For these interrupts, there is no software clear mechanism by writing to ADCn_IFC. The user needs to read enough data from the interrupted FIFO to ensure it contains less than DVL # of elements. The ADCn_SINGLEFIFOCOUNT/ADCn_SCANFIFOCOUNT can provide number of valid elements remaining in corresponding FIFO. The FIFO can also be cleared by ADCn_SINGLEFIFOCLEAR/ADCn_SCANFIFOCLEAR, but any existing data will be lost by this operation.

In addition to the SINGLE and SCAN interrupt flags, there is separate scan and single channel result overflow interrupt flag which signals that a result from a scan or single channel FIFO has been overwritten before being read. There is also separate scan and single channel result underflow interrupt flag which signals that a FIFO read was issued when the FIFO was empty.

There is separate scan and single compare interrupt flag which signals a compare match with latest sample if the CMPEN in ADCn_SINGLECTRL/ADCn_SCANCTRL is enabled.

ADC has two separate PRS outputs, one for single channel and one for scan sequence. A finished conversion results in a one ADC_CLK cycle pulse, which is output to the Peripheral Reflex System (PRS). Note that the PRS pulse for scan is generated once after every channel conversion in the scan sequence.

# 26.3.12 DMA Request

The ADC has two DMA request lines, SINGLEREQ and SCANREQ, which are set when a single or scan FIFO receives DVL# of samples. The requests are cleared when the corresponding single or scan result register is read and corresponding FIFO count reaches lower than DVL. It also has two additional DMA Single request lines, SINGLESREQ and SCANSREQ, that are set when the corresponding FIFO is not empty.

## 26.3.13 Calibration

The ADC supports offset and gain calibration to correct errors due to process and temperature variations. This must be done individually for each reference used. For each reference, it needs to be repeated for single-ended, negative single-ended (see 26.3.7 Input Selection for details) and differential measurement. The ADC calibration (ADCn_CAL) register contains register fields for calibrating offset and gain for both single and scan mode. The gain and offset calibration are done in single channel mode, but the resulting calibration values can be used for both single and scan mode.

Gain and offset for various references and modes are calibrated during production and the calibration values for these can be found in the Device Information page. During reset, the gain and offset calibration registers are loaded with the production calibration values for the 1V25 reference. Others can be loaded as needed or the user can perform calibration on the fly using the particular reference and mode to be used and write the result in the ADCn CAL before starting the ADC conversion with them.

# 26.3.13.1 Offset Calibration

Offset calibration must be performed prior to gain calibration. Follow these steps for the offset calibration in single mode:

- 1. Select the desired full scale configuration by setting the REF bit field of the ADCn SINGLECTRL register.
- 2. Set the AT bit field of the ADCn SINGLECTRL register to 16CYCLES.
- 3. Set the POSSEL and NEGSEL of the ADCn_SINGLECTRL register to VSS, and set the DIFF to 1 for enabling differential input if calibrating for DIFF measurement. During calibration, the ADC samples represent the code coming out of the analog. Thus, since the input voltage is 0, the expected ADC output is 0b100000000000 in differential mode, 0b000000000000 in single-ended mode and 0b11111111111 in negative single-ended mode.
- 4. A binary search is used to find the offset calibration value. Set the CALEN to 1, and OFFSETINVMODE to 1 (if calibrating for negative single-ended conversion) in the ADCn_CAL register. If user is performing negative single-ended calibration, the SINGLEOFFSETINV provides the offset else SINGLEOFFSET bit provides the offset (for both single-ended and differential offset calibration). Start with 0b0000 (or 0b1111 if doing calibration for differential mode) in SINGLEOFFSET or with 0b1000 in SINGLEOFFSETINV (if calibrating for negative single-ended conversion). Set the SINGLESTART bit in the ADCn_CMD register to perform a 12-bit conversion and read the ADCn_SINGLEDATA register. The offset is (ADCn_SINGLEDATA expected ADC output). Calculate this and write [3:0] of the result into SINGLEOFFSET or SCANOFFSETINV (if doing negative single-ended conversion). The user repeats till ADCn_SINGLEDATA matches expected ADC output. The ADC has a 8LSB built in negative offset to allow for negative offset correction. So, with default offset value, which corrects for the negative offset, the converted ADCn_SINGLEDATA would match expected ADC output if there were no offset. To get better noise immunity, the sampling phase can be repeated with Oversampling enabled. The result of the binary search is written to the SINGLEOFFSET (or SINGLEOFFSETINV) field of the ADCn_CAL register.

### 26.3.13.2 Gain Calibration

Offset calibration must be performed prior to gain calibration. The Gain Calibration is done in the following manner:

- 1. Select an external ADC channel for single channel conversion (a differential channel can also be used).
- Apply an external voltage on the selected ADC input channel. This voltage should correspond to the top of the ADC input range for the selected reference.
- 3. Set SINGLEGAIN[6:0] to 64 in the ADCn_CAL and measure gain, repeat gain calibration walking the 1 in SINGLEGAIN[6] to SINGLEGAIN[0] till sampled ADCn_SINGLEDATA matches expected value. This is done by setting CALEN in ADCn_CAL set to 1 and performing single channel, reading in the raw ADC code from the ADCn_SINGLEDATA and comparing it with expected code, i.e. 0b111111111111 for single-ended or differential conversion, and 0b000000000000 for negative single-ended conversion. The target value is ideally the top of the ADC input range, but it is recommended to use a value a couple of LSBs below in order to avoid overshooting. The result of the binary search is written to the SINGLEGAIN field of the ADCn_CAL register.

For the VDD reference and external reference, there is no hardware gain calibration. Calibration can be done by software after taking a sample.

# 26.3.14 EM2 Deep Sleep or EM3 Stop Operation

The ADC can operate in EM2 Deep Sleep or EM3 Stop mode. For EM2 Deep Sleep or EM3 Stop operation the ADC_CLK must be selected as AUXHFRCO. The section 26.3.1 Clock Selection describes how to choose AUXHFRCO as the ADC_CLK. The AUXHFRCO can be kept on for as long as sample conversion is needed or it can be requested by trigger event and after the conversion is done, the AUXHFRCO can be shut down. The second option saves power at the expense of the delay to start the AUXHFRCO oscillator. All the trigger modes are available in EM2 Deep Sleep or EM3 Stop as well.

While in EM2 Deep Sleep or EM3 Stop, the ADC can wake the system to EM0 Active on enabled interrupts. Following interrupts can wake up the system to EM0 Active:

- SINGLE or SCAN interrupt indicating that the corresponding FIFO has reached the DVL watermark.
- Overflow interrupt (SINGLEOF or SCANOF)
- Underflow interrupt (SINGLEUF or SCANUF), triggered if DMA pops more data than present in the FIFO while the system is asleep
- · Compare interrupt (SINGLECMP or SCANCMP)
- Over voltage interrupt (VREFOV)

The ADC can also work with the DMA so that the system does not have to wake up to consume data. This can happen if the SCAN or SINGLE interrupt is disabled and the SINGLEDMAWU or SCANDMAWU in the ADCn_CTRL is set. The DMA will be triggered by the ADC when DVL samples become available in the corresponding FIFO. The DMA will then pop all the elements of the corresponding FIFO and put the system back into the low power state. A system-level wake up will occur upon the DMA done interrupt. Note that other enabled ADC interrupts can still wake up the system when operating with the DMA. For example, the user can configure the window compare function to trip when the result reaches a certain threshold while gathering ADC data in EM2 Deep Sleep or EM3 Stop.

The ADC works with the EMU to wake up the system or the DMA. It takes 2 µs from the time the ADC request a wakeup to start of the peripheral clocks. In this ASYNC mode of ADC_CLK, it takes 6 HFPERCLK cycles to read a single entry from the single or scan FIFO. So, with a 20MHz HFPERCLK, it takes about 4 µs per DMA wakeup to empty a full FIFO (4 entries). This restricts the sampling rate in EM2 Deep Sleep or EM3 Stop in order to avoid FIFO overflows.

The AUXHFRCO power can be reduced by reducing the clock speed, and the user may adjust the ADCBIASPROG field in the ADCn_BIASPROG register to reduce active power of the ADC during the conversions, thus reducing power even more in EM2 Deep Sleep/EM3 Stop. Refer to the data sheet for relevant power consumption numbers.

If the ADC is not to be used in EM2 Deep Sleep or EM3 Stop, then the user should ensure that the ADC is not busy before going to the low power mode. 26.3.17 ADC Programming Model explains how to ensure the ADC is not busy. If the chip enters EM2 Deep Sleep or EM3 Stop when ADC is busy without using AUXHFRCO, then the ADC clock will stop but the ADC will stay on, resulting in higher supply current. If this occurs, the EM23ERR interrupt flag will be set. Software will see this interrupt flag only when the chip wakes up.

# 26.3.15 ASYNC ADC_CLK Usage Restrictions and Benefits

When the ADC_CLK is chosen to come from ASYNCCLK, (ADCCLKMODE is set to ASYNC), the ADC_CLK and the ADC peripheral clock are considered asynchronous and this adds some restrictions:

- Due to a synchronization delay, accessing the following registers takes extra time (up to additional 7 HFPERCLK cycles):
   ADCn_SINGLEDATA, ADCn_SCANDATA, ADCn_SINGLEDATAP, ADCn_SCANDATAP, ADCn_SCANDATAX, ADCn_SCANDATAXP, ADCn_SINGLEFIFOCOUNT, ADCn_SCANFIFOCOUNT, ADCn_SINGLEFIFOCLEAR, ADCn_SCANFIFOCLEAR.
- The safe time to change the ADCn_SINGLECTRL, ADCn_SINGLECTRLX, ADCn_SCANCTRL, ADCn_SCANCTRLX, ADC
- When the ADC needs to run in EM2 Deep Sleep or EM3 Stop, only AUXHFRCO can provide the ADC_CLK to the ADC. Thus the
  user needs to set ASYNC mode of ADCCLKMODE and setup the CMU to provide the AUXHFRCO clock as ASYNCCLK.
- If the ADC needs to run on a particular adc_clk_sar frequency to achieve a sample rate and the HFPERCLK is not a proper multiple
  for such clock frequency, a higher frequency system clock, HFRCO, can be chosen to be ADC_CLK using ASYNC mode. This allows HFPERCLK to be set to an optimum value from a system view point.
- ASYNC mode can also help with digital noise mitigation as this clock is asynchronous (not balanced) with the system clock. Moreover, the user can use the invert option to invert the source of ASYNCCLK helping in noise mitigation further.
- Whenever ADC is being used in asynchronous mode, then HFPERCLK must be at least 1.5 times higher than the ADC_CLK.
- With ASNEEDED setting for ASYNCCLK request, the ADC_CLK power can be reduced.

# 26.3.16 Window Compare Function

The ADC supports a window compare function on both the latest single and scan outputs. The compare thresholds, ADGT and ADLT, are defined in the ADCn_CMPTHR register. These are 16-bit values and their format must match the type of conversion (single-ended or differential) the user is trying to compare with. For example, a 12-bit differential conversion is sign extended to 16 bits while a 12-bit single-ended conversion result would get zero padded to 16-bit result before comparing with ADGT and ADLT. If over-sampling is enabled, the conversion result could grow to 16-bits. There is a single set of ADLT and ADGT threshold for both single and scan compare. The user can however enable single or scan compare logic individually by enabling CMPEN in ADCn_SINGLECTRL or ADCn_SCANCTRL register.

The user can perform comparison both within or outside of the window defined by the ADGT and ADLT. If the ADLT is greater than ADGT, the ADC compares if the current sample is within the window. Otherwise, the ADC compares if the current sample is outside of the window.

## 26.3.17 ADC Programming Model

The ADC configuration registers are considered static and can only be updated when (1) ADC is in SYNC mode and (2) ADC is idle. ADC is considered busy when it is doing conversions (either the SINGLEACT or SCANACT status flag is high) or when it is warmed up (one of the following status flags is high: WARM, SINGLEREFWARM, SCANREFWARM). The following registers are considered ADC configuration registers: CMU_ADCCTRL, ADCn_CTRL, ADCn_SINGLECTRLX, ADCn_SINGLECTRLX, ADCn_SCANCTRL, ADCn_SCANCTRL, ADCn_SCANCTRLX, ADCn_SCANINPUTSEL, ADCn_SCANNEGSEL, ADCn_IEN, ADCn_BIASPROG, ADCn_SCANMASK, ADCn_CAL and ADCn_CMPTHR.

From reset, the ADC is in SYNC mode by default. The user can program the configuration registers as needed. If PRS is to be used, PRSEN in ADCn_SINGLECTRL/ADCn_SCANCTRL should be set after all other configuration is complete. Once configuration is complete, the ADC is ready to receive triggers. The user must ensure that no LESENSE triggers come in during the time the ADC configuration registers are being updated.

After the ADC has been used to perform conversions, the user must ensure that the ADC is idle before updating the configuration registers. The first step is to ensure that no new triggers (PRS, LESENSE) are being issued. It can take a few cycles from when a trigger is received to when SINGELACT/SCANACT flags go high due to synchronization requirement. If it is unclear when the triggers were issued and if those are under synchronization or not, the user should add a small delay before checking the status flags. If the SINGLE-ACT/SCANACT status flags are high, the corresponding STOP command should be issued and the user should wait until the SINGLE-ACT/SCANACT flags go low. If the ADC was warmed up, then the WARMUPMODE should be changed to NORMAL and then the user should wait on WARM, SINGLEREFWARM and SCANREFWARM flags until those go low. Now the ADC is idle.

If both LESENSE scan and PRS/software scan conversions are taking place, then since there are two scans occurring, the SCAN STOP command needs to be issued twice. The user can check the SCANPENDING status flag. If the flag is set then the user needs to send out 2 SCAN STOP commands. After sending out the first SCAN STOP, the user needs to wait until the SCANPENDING flag goes low. Then the second SCAN STOP command should be issued and the user should wait on the SCANACT status flag to go low.

#### Note:

When switching ADCCLKMODE in the ADCn_CTRL register, use the appropriate sequence below:

- SYNC to ASYNC:
  - 1. Disable ADC interrupts
  - 2. Clear the FIFOs
  - 3. Switch the ADCCLKMODE

If the ADC is to be used in ASYNC clock mode with WARMUPMODE set to KEEPADCWARM, then both ADCCLKMODE and WARMUPMODE fields in the ADCn_CTRL register should be set to the desired values in the same register write. This will ensure that the ADC power-on sequence is valid.

- ASYNC TO SYNC:
  - 1. Disable ADC interrupts
  - 2. Switch the ADCCLKMODE
  - 3. Clear the FIFOs

The FIFOs are cleared by writing 1 to the ADCn_SCANFIFOCLEAR and ADCn_SINGLEFIFOCLEAR registers.

When switching from ASYNC to SYNC, ensure that the ASYNC clock is turned off before doing the switch.

# 26.4 Register Map

128 conversion clock cycles acquisition time for single channel

256 conversion clock cycles acquisition time for single channel

Bit	Name	Reset	Access	Description
23:16	NEGSEL	0xFF	RW	Single Channel Negative Input Selection

Selects the negative input to the ADC for Single Channel Differential mode (in case of singled ended mode, the negative input is grounded). The user can choose any of the 32 channels of any of the 5 BUSes but must ensure that POSSEL and NEGSEL are chosen from different resources (X or Y) BUS. In case of an invalid configuration, the ADC will perform a single-ended sampling and issue a BUSCONFLICT IRQ.

POSSEL	0xFF	RW	Single Channel Positive Input Selection

Selects the positive input to the ADC for single channel operation. Software can choose any of the 32 channels of any BUS as positive input. In DIFF mode POSSEL and NEGSEL need to be chosen from different resources (X or Y). If an X BUS is connected to POSSEL, only a Y BUS can connect to NEGSEL, and vice-versa. The user can also select some internal nodes as positive input for single-ended sampling. These internal nodes cannot be sampled differentially.

	11	PRSCH11	PRS ch 11 triggers scan sequence
16	PRSMODE	0 RW	Scan PRS Trigger Mode
	PRS trigger mode	e of scan.	
	Value	Mode	Description
	0	PULSED	Scan trigger is considered a regular async pulse that starts ADC warm-up, then acquisition/conversion sequence. The ADC_CLK controls the warmup-time.
	1	TIMED	Scan trigger should be a pulse long enough to provide the required warm-up time for the selected ADC warmup mode. The negative edge requests sample acquisition. DELAY can be used to delay the warm-up request if the pulse is too long.
15	Reserved	To ensure compatibility tions	with future devices, always write bits to 0. More information in 1.2 Conven-
14	FIFOOFACT	0 RW	Scan FIFO Overflow Action
	Select how FIFO	behaves when full	
	Value	Mode	Description
	0	DISCARD	FIFO stops accepting new data if full, triggers SCANOF IRQ.
	1	OVERWRITE	FIFO overwrites old data when full, triggers SCANOF IRQ.
13:12	DVL	0x0 RW	Scan DV Level Select
		Valid level. SCAN IRQ is set ble in the SCAN FIFO.	when (DVL+1) number of scan channels have been converted and their

Bit	Name	Reset	Access	Description
11:8	VINATT	0x0	RW	Code for VIN Attenuation Factor
	Used to set the V	IN attenuation factor.		
7:4	VREFATT	0x0	RW	Code for VREF Attenuation Factor When VREFSEL is 1, 2 or 5
	Used to set VREF	attenuation factor.		
3	VREFATTFIX	0	RW	Enable Fixed Scaling on VREF
	Enables fixed sca	lling on VREF		
	Value			Description
	0			VREFATT setting is used to scale VREF when VREFSEL is 1, 2 or 5.
	1			A fixed VREF attenuation is used to cover a large reference source range. When VREFATT = 0, the scaling factor is 1/4. For non-zero values of VREFATT, the scaling factor is 1/3.
2:0	VREFSEL	0x0	RW	Scan Channel Reference Selection
	Select reference	VDEE to ADC soon of	nannel mo	ode.

Bit	Na	me					Re	set			Acc	cess	Des	crip	tion															

Set one or more bits in this mask to select which inputs are included in scan sequence in either single ended or differential mode. This works with SCANINPUTSEL register. The SCANINPUTSEL chooses 32 possible channels for single-ended or 32 pairs of possible channels for differential scanning from BUSes. These chosen channels are referred as ADCn_INPUTx in the description. Four even inputs from first group of 8 ADCn_INPUTx and four odd inputs from second group of 8 ADCn_INPUTx have programmable NEGSEL, defined in SCANNEGSEL register. If the SCANMASK is set to 0 and scan conversion is triggered, ADC will do a conversion with garbage results since no inputs were enabled for conversion.

# 27. IDAC - Current Digital to Analog Converter

#### **Quick Facts**

#### What?

The IDAC can sink or source a configurable constant current.

## Why?

The IDAC can be used to bias external circuits or (in conjunction with the ADC) measure capacitance by injecting a controlled current into a component.

#### How?

In addition to providing a constant current, the IDAC can be switched on and off with a PRS signal all the way down to EM3.

#### 27.1 Introduction

The current digital to analog converter (IDAC) can source or sink a configurable constant current from APORT and/or main pad (OUT-PAD). The current is configurable with several ranges of various step sizes.

#### 27.2 Features

- · Can source and sink current
- · Programmable constant output current
  - Selectable current range between 0.05 μA and 64 μA
  - Each range is linearly programmable in 32 steps
  - · Support for current calibration
- Support for manual and PRS triggered output enable
- Available in EM0-EM3

## 27.3 Functional Description

An overview of the IDAC module is shown in Figure 27.1 IDAC Overview on page 943. The IDAC is designed to source or sink a programmable current which can be controlled by setting the range and the step in the RANGESEL and STEPSEL bitfields in IDAC_CURRPROG register. The IDAC output enable can be controlled by software or PRS. The IDAC is enabled by setting EN in IDAC_CTRL.

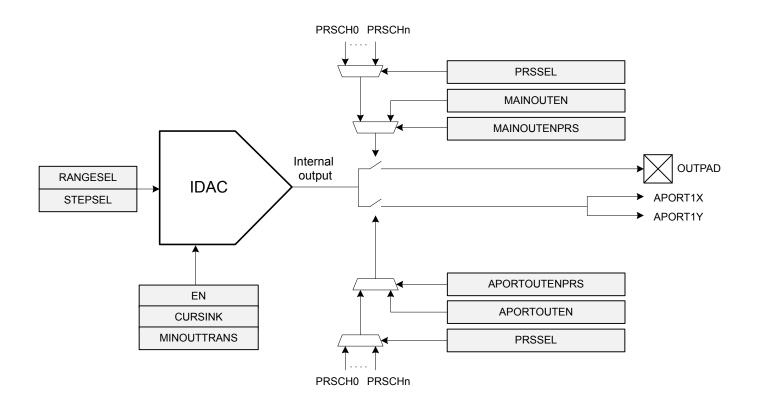

Figure 27.1. IDAC Overview

# 27.3.1 Current Programming

The four different current ranges can be selected by configuring the RANGESEL bitfield in IDAC_CURRPROG. The current output in each range is linearly programmable in 32 steps, and is controlled by the STEPSEL bitfield in IDAC_CURRPROG. These current ranges and their step sizes are shown in Table 27.1 Range Selection on page 943.

Range Select Range Value [µA] Step Size [nA] **Step Counts** 0 0.05 - 1.632 50 1 1.6 - 4.7100 32 2 0.5 - 16500 32 3 2 - 64 2000 32

Table 27.1. Range Selection

## 27.3.2 IDAC Enable and Warm-up

The IDAC is enabled by setting the EN bit in IDAC_CTRL. When this bit is set, the IDAC must stabilize before its output current is stable.

It is important to wait until the IDAC is warmed up, or until any current programming is complete and the output current is stabilized, before entering EM1, EM2, or EM3.

#### 27.3.3 Output Control

The IDAC output enable is controlled separately for APORT and main pad. If APORTOUTENPRS/MAINOUTENPRS is set, output enable is controlled by PRS, else it is controlled by software via APORTOUTEN/MAINOUTEN.

## 27.3.4 APORT Configuration

The IDAC APORT outputs can be routed to pins through the APORT system. Note that the IDAC has only two local APORT interfaces APORT1X and APORT1Y, which are connected to the APORT BUSCX and BUSCY, respectively. The pins are selected by requesting an APORT channel in APORTOUTSEL in IDAC_CTRL. For mapping between APORT channel and physical pin, please refer to data sheet. The IDAC can be in either master or slave mode when connecting to the APORT. By default the IDAC is in master mode. To enable slave mode, set APORTMASTERDIS in IDAC_CTRL. As IDAC is only capable of driving an APORT channel, only master mode is meaningful for IDAC. If the IDAC is in master mode, and another module is currently driving the requested channel, the APORTCONFLICT bitfield in IDAC_STATUS will be set together with APORT1XCONFLICT or APORT1YCONFLICT in IDAC_APORTCONFLICT. The APORTCONFLICT can also be configured to trigger an interrupt, see 27.3.5 Interrupts for details.

## 27.3.5 Interrupts

The APORTCONFLICT interrupt flag in the IDAC_IF register indicates that a conflict has occurred when requesting a channel from the APORT. The APORTCONFLICT interrupt can be enabled by setting the APORTCONFLICT bit in IDAC_IEN, or cleared by setting the APORTCONFLICT bit in IDAC_IFC.

## 27.3.6 Minimizing Output Transition

If the internal output of the IDAC differs from the voltage at the output pin, enabling the output can cause an unwanted transition. To minimize this transition, it is possible to charge or discharge the internal output node before enabling the output to the pin. Setting MINOUTTRANS in IDAC_CTRL when the IDAC is sourcing current connects the internal node to GND. Alternatively, setting MINOUTTRANS when the IDAC is sinking current connects the internal output node to VDD. Setting APORTOUTEN/MAINOUTEN when MINOUTTRANS is set will halt the charge/discharge until either APORTOUTEN/MAINOUTEN is cleared or MINOUTTRANS is cleared.

## 27.3.7 Duty Cycle Configuration

The references for the IDAC can be duty-cycled, meaning that it can source current at very low overhead current consumption at the cost of response time and accuracy. By default duty-cycling is enabled in EM2 and EM3 and disabled in EM0 and EM1. Setting EM2DUTYCYCLEDIS in IDAC_DUTYCONFIG will disable duty cycling in EM2 and EM3. Note that sinking current can not be done with duty-cycled references so measures needs to be taken to always disable duty-cycling while sinking current.

# 27.3.8 Calibration

The IDAC can be calibrated to accurately compensate for process, supply voltage and temperature variations. During the production test, the middle step of each range is calibrated at room temperature. The TUNING bitfield in the IDAC_CAL register can be used to do further calibration of each step with an external resistor connected to IDAC_OUT. The calibrated tuning value for each band can be read from the Device Information (DI) page.

## 27.3.9 PRS Triggered Charge Injection

The amount of charge sourced or sunk by the IDAC can be controlled by the PRS (e.g., using a timer as producer) via the output switch. Figure 27.2 IDAC Charge Injection Example on page 945 shows a case where the IDAC is configured to periodically supply charge using the PRS. The amount of charge injected is proportional to the the period the IDAC is on. The total charge injected is the current multiplied by the time the output switch is enabled.

The PRS system is enabled by setting APORTOUTENPRS/MAINOUTENPRS in IDAC_CTRL, and the PRS channel is selected by PRSSEL in IDAC_CTRL. To generate the periodic control signal, the TIMER module can be used, by configuring for example a CC channel to compare match with a configurable level.

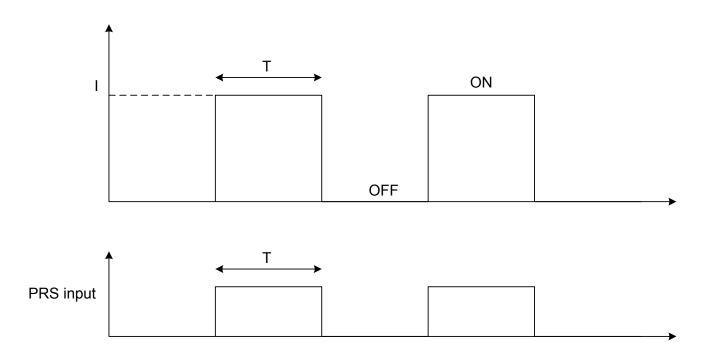

Figure 27.2. IDAC Charge Injection Example

## 27.4 Register Map

# 28. LESENSE - Low Energy Sensor Interface

#### **Quick Facts**

#### What?

LESENSE is a low energy sensor interface capable of autonomously collecting and processing data from multiple sensors even when in EM2. Flexible configuration makes LESENSE a versatile sensor interface compatible with a wide range of sensors and measurement schemes.

## Why?

Capability to autonomously monitor sensors allows the EFR32xG12 Wireless Gecko to reside in a low energy mode for long periods of time while keeping track of sensor status and sensor events.

#### How?

LESENSE is highly configurable and is capable of collecting data from a wide range of sensor types. Once the data is collected, the programmable state machine, LESENSE decoder, is capable of processing sensor data without CPU intervention. A large result buffer allows the chip to remain in EM2 for long periods of time while autonomously collecting data.

## 28.1 Introduction

LESENSE is a low energy sensor interface utilizing on-chip peripherals to perform measurement of a configurable set of sensors. The sensor measurements results can be processed by the LESENSE decoder, a configurable state machine with up to 32 states. The results can also be stored in a result buffer to be collected by the CPU or DMA for further processing.

LESENSE operates from EM0 down to EM2, and can wake up the CPU on configurable events.

#### 28.2 Features

- · Up to 16 sensors
- Autonomous sensor monitoring in EM0, EM1, and EM2
- · Highly configurable decoding of sensor results
- · Interrupt on sensor events
- · Configurable enable signals to external sensors
- · Circular buffer for storage of up to 16 sensor results
- · Multiple evaluation modes minimize the need for software interaction
- · Supports ADC0 sampling and evaluation
- · Support for multiple sensor types
  - · LC sensors
  - · Capacitive sensing
  - · General analog sensors

#### 28.3 Functional Description

The LESENSE module is capable of controlling on-chip peripherals in order to perform monitoring of different sensors with little or no CPU intervention. LESENSE uses the analog comparators (ACMP) or ADC0 for measurement of sensor signals. LESENSE can also control the VDAC to generate accurate reference voltages. Figure 28.1 LESENSE Block Diagram on page 954 shows an overview of the LESENSE module.

The LESENSE module consists of a sequencer, an evaluation block, a decoder, and a RAM block:

- The sequencer handles interaction with other peripherals and controls timing of sensor measurements. It also includes a counter that can be used to count pulses on the ACMP output.
- The evaluation block is used to process the data collected by the sequencer.
- To autonomously analyze sensor results, the LESENSE decoder provides the ability to define a finite state machine with up to 32 states, as well as define programmable actions upon state transitions. This allows the decoder to implement a wide range of decoding schemes, such as quadrature decoding.
- A RAM block is used for storage of configuration and measurement results. This allows LESENSE to have a relatively large result buffer enabling the chip to remain in a low energy mode for long periods of time while collecting sensor data.

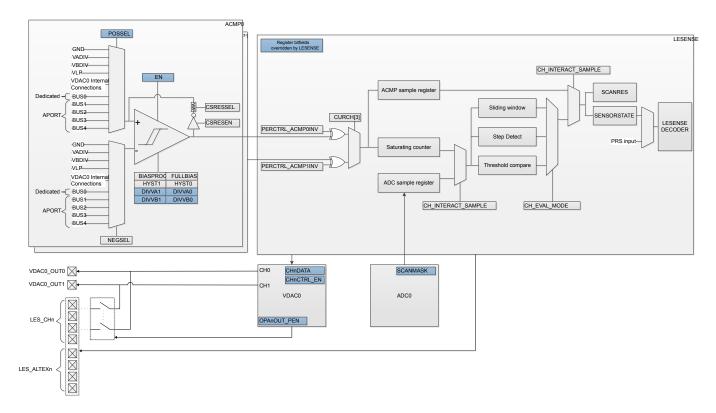

Figure 28.1. LESENSE Block Diagram

#### 28.3.1 Channel Configuration

LESENSE has 16 individually configurable channels, each with its own set of configuration registers. Channel configuration is split into three registers; CHx_TIMING, CHx_INTERACT, and CHx_EVAL. Individual timing for each sensor is configured in CHx_INTERACT, and configurations regarding evaluation of the measurements are done in CHx_EVAL. For improved readability, CHx_CONF will be used to refer to the channel configuration registers (CHx_TIMING, CHx_INTERACT, and CHx_EVAL) throughout this chapter.

By default, the channel configuration registers are directly mapped to the channel number. Configuring SCANCONF in CTRL makes it possible to alter this mapping.

Configuring SCANCONF to INVMAP will make channels 0-7 use the channel configuration registers for channels 8-15, and vice versa. This feature allows an application to quickly and easily switch the configuration set for the channels.

Setting SCANCONF to TOGGLE will make channel x alternate between using  $CH_{X-S}$ CONF and  $CH_{X+8}$ CONF. The configuration used is decided by the state of the corresponding bit in SCANRES. For instance, if channel 3 is performing a scan and bit 3 in SCANRES is set,  $CH_{11}$ CONF will be used. Channels 8 through 15 will toggle between  $CH_{X}$ CONF and  $CH_{X-8}$ CONF. This mode provides an easy way to implement hysteresis on channel events, as threshold values can be changed depending on the sensor status.

Setting SCANCONF to DECDEF will make the state of the decoder define which scan configuration to be used. If the decoder state is at index 16 or higher, channel x will use  $CH_{X+8}$ _CONF, otherwise it will use  $CH_{X}$ _CONF. Similarly, channels 8 through 15 will use  $CH_{X}$ _CONF when the decoder state index is less than 8 and  $CH_{X-8}$ _CONF when the decoder state index is higher than 7. Allowing the decoder state to define which configuration to use enables easy implementation of hysteresis, for example, as different threshold values can be used for the same channel depending on the state of the application. Table 28.1 LESENSE Scan Configuration Selection on page 955 summarizes how channel configuration is selected for different settings of SCANCONF.

**SCANCONF LESENSE TOGGLE DECDEF** channel x DIRMAP INVMAP SCANRES[n] = 0SCANRES[n] = 1DECSTATE < 16 DECSTATE >= 16  $0 \le x \le 8$ CH_x_CONF CH_{x+8}_CONF CH_x_CONF CH_{x+8}_CONF CH_x_CONF CH_{x+8}_CONF  $8 \le x \le 16$ CH_x_CONF CH_{x-8}_CONF CH_x CONF CH_{x-8}_CONF CH_x CONF CH_{x-8}_CONF

**Table 28.1. LESENSE Scan Configuration Selection** 

Channels are enabled in the CHEN register, where bit x enables channel x. During a scan, all enabled channels are measured, starting with the lowest indexed channel. Figure 28.3 Scan Sequence on page 956 illustrates a scan sequence with channels 3, 5, and 9 enabled.

#### 28.3.2 Scan Sequence

LESENSE runs on LFACLK_{LESENSE}, which is a prescaled version of LFACLK. The prescaling factor for LFACLK_{LESENSE} is selected in the CMU, available prescaling factors are:

- DIV1: LFACLK_{LESENSE} = LFACLK/1
- DIV2: LFACLK_{LESENSE} = LFACLK/2
- DIV4: LFACLK_{LESENSE} = LFACLK/4
- DIV8: LFACLK_{I ESENSE} = LFACLK/8

All enabled channels are scanned each scan period. How a new scan is started is configured in the SCANMODE bit field in CTRL. If set to PERIODIC, the scan frequency is generated using a counter which is clocked by LFACLK_{LESENSE}. This counter has its own prescaler. This prescaling factor is configured in PCPRESC in TIMCTRL. A new scan sequence is started each time the counter reaches the top value, PCTOP. The scan frequency is calculated using Figure 28.2 Scan Frequency on page 956. If SCANMODE is set to ONE-SHOT, a single scan will be made when START in CMD is set. To start a new scan on a PRS event, set SCANMODE to PRS and configure PRS channel in PRSSEL. The PRS start signal needs to be active for at least one LFACLK_{LESENSE} cycle to make sure LE-SENSE is able to register it.

Figure 28.2. Scan Frequency

It is possible to interleave additional sensor measurements in between the periodic scans. Issuing a start command when LESENSE is idle will immediately start a new scan, without disrupting the frequency of the periodic scans. If the period counter overflows during the interleaved scan, the periodically scheduled scan will start immediately after the interleaved scan completes.

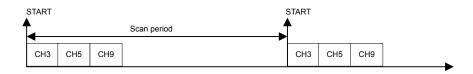

Figure 28.3. Scan Sequence

#### 28.3.3 Sensor Timing

For each channel in the scan sequence, the LESENSE interface goes through three phases: idle, excite, and measure. The durations of the excite and measure phases are configured in the CHx_TIMING registers. The excite phase duration can be configured to be either a number of AUXHFRCO cycles or a number of LFACLK_{LESENSE} cycles, depending on which one is selected by the EXCLK bit in the CHx_INTERACT register. LESENSE includes two timers: A low frequency timer, running on LFACLK_{LESENSE}, and a high frequency timer, running on AUXHFRCO. The low frequency or high frequency timers can be prescaled by configuring LFPRESC or AUXPRESC, respectively, in the TIMCTRL register. The duration of the measure phase is programmed via MEASUREDLY and SAMPLEDLY in the CHx_TIMING registers. The output of the ACMP will be ignored for MEASUREDLY EXCLK cycles after start of the sensor measurement. Sampling of the sensor will happen after SAMPLEDLY LFACLK_{LESENSE}, or AUXHFRCO cycles, depending on the configuration of the SAMPLECLK in the CHx_INTERACT register. The configurable measure- and sample delays enables LESENSE to easily define exact time windows for sensor measurements. A start delay can be inserted before sensor measurement begin by configuring STARTDLY in TIMCTRL. This delay can be used to ensure that the VDAC conversion is done and voltages have stabilized before the sensor measurement begins. The AUXHFRCO startup can be delayed until the system enters the excite phase, by configuring AUX-STARTUP in TIMCTRL to ONDEMAND. This will reduce the time the AUXHFRCO is enabled and reduce power consumption, with the tradeoff that that the starting point for high frequency timing will also be delayed the same amount as the AUXHFRCO startup time.

Figure 28.4 Timing Diagram, AUXHFRCO Based Timing on page 957 depicts a sensor sequence with AUXHFRCO based timing (EXTIME=5, MEASUREDLY=7, SAMPLEDLY=13), while Figure 28.5 Timing Diagram, LFACLK Based Timing on page 958 depicts a sequence with LFACLK_{LESENSE} based timing (EXTIME=1, MEASUREDLY=1, SAMPLEDLY=2).

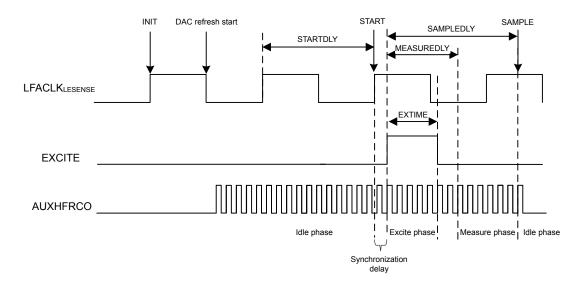

Figure 28.4. Timing Diagram, AUXHFRCO Based Timing

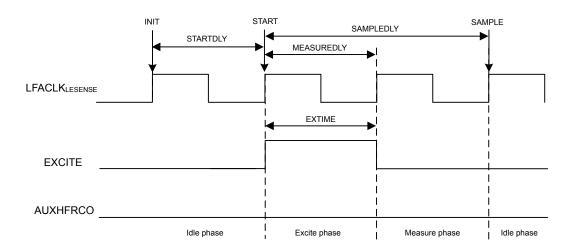

Figure 28.5. Timing Diagram, LFACLK Based Timing

#### 20.3.4 Sensor interaction

Many sensor types require some type of excitation in order to work. The LESENSE module can generate a variety of sensor stimuli, both on the same pin as the measurement is to be made on, as well as alternative pins.

By default, excitation is performed on the pin associated with the channel (i.e., excitation and sensor measurement is performed on the same pin). The mode of the pin during the excitation phase is configured by the EXMODE bitfield in CHx_INTERACT. The available modes during the excite phase are:

- · DISABLED: The pin is disabled.
- · HIGH: The pin is driven high.
- · LOW: The pin is driven low.
- DACOUT: The pin is connected to the output of a VDAC channel.

**Note:** Excitation with VDAC output is only available on some channels. Refer to 28.3.9 VDAC Interface for details. If the VDAC is in opamp-mode, setting EXMODE to DACOUT will result in excitation with output from the opamp.

LESENSE is able to perform sensor excitation on a pin other than the one being measured. When ALTEX in CHx_INTERACT is set, the excitation will occur on the alternative excite pin associated with the given channel. By default, the alternative excite pins are mapped to the LES_ALTEX pins, but they can also be mapped to LESENSE  $CH_{X+8 \mod 16}$ . Mapping of the alternative excite pins is configured in ALTEXMAP in the CTRL register. Table 28.2 LESENSE Excitation Pin Mapping on page 959 summarizes the mapping of excitation pins for different configurations.

Table 28.2. LESENSE Excitation Pin Mapping

LESENSE channel	ALTEX = 0	ALTEX = 1		
		ALTEXMAP = CH	ALTEXMAP = ALTEX	
0	LES_CH0	LES_CH8	LES_ALTEX0	
1	LES_CH1	LES_CH9	LES_ALTEX1	
2	LES_CH2	LES_CH10	LES_ALTEX2	
3	LES_CH3	LES_CH11	LES_ALTEX3	
4	LES_CH4	LES_CH12	LES_ALTEX4	
5	LES_CH5	LES_CH13	LES_ALTEX5	
6	LES_CH6	LES_CH14	LES_ALTEX6	
7	LES_CH7	LES_CH15	LES_ALTEX7	
8	LES_CH8	LES_CH0	LES_ALTEX0	
9	LES_CH9	LES_CH1	LES_ALTEX1	
10	LES_CH10	LES_CH2	LES_ALTEX2	
11	LES_CH11	LES_CH3	LES_ALTEX3	
12	LES_CH12	LES_CH4	LES_ALTEX4	
13	LES_CH13	LES_CH5	LES_ALTEX5	
14	LES_CH14	LES_CH6	LES_ALTEX6	
15	LES_CH15	LES_CH7	LES_ALTEX7	

Figure 28.6 Pin Sequencing on page 960 illustrates the sequencing of the pin associated with the active channel and its alternative excite pin.

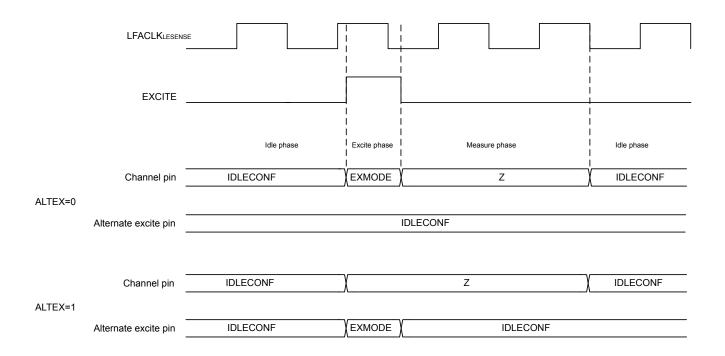

Figure 28.6. Pin Sequencing

The LES_ALTEXn pins have the ability to excite regardless of what channel is active. Setting AEXn in ALTEXCONF will make LES_ALTEXn excite for all channels using alternative excitation (i.e., ALTEX in CHx INTERACT is set).

**Note:** When exciting on the pin associated with the active channel, the pin will go through a tri-stated phase before returning to the idle configuration. This will not happen on pins used as alternative excitation pins.

The pin configuration for the idle phase can be configured individually for each LESENSE channel and alternative excite pin in the IDLECONF and ALTEXCONF registers. The modes available are the same as the modes available in the excitation phase. In the measure phase, the pin mode on the active channel is always disabled (analog input).

To allow the LESENSE mode to control a GPIO pin, the pin must be enabled in the ROUTEPEN register and configured as push-pull. The IDLECONF configuration should not be altered while the pin enable for a given pin is set in ROUTEPEN.

#### 28.3.5 Sensor Sampling

During the measurement phase, LESENSE can sample data from sensors using either ADC0 or an ACMP. This is configured in CHx_INTERACT_SAMPLE. If the ACMP is used, LESENSE can evaluate the ACMP output at a single point in time (CHx_INTERACT_SAMPLE = ACMPCOUNT) for a programmable period of time.

LESENSE includes the ability to sample both analog comparators simultaneously, effectively cutting the time spent on sensor interaction in some applications in half. Setting DUALSAMPLE in CTRL enables this mode. In dual sample mode, channels X and X+8 are paired, meaning they will be sampled at the same time. DUALSAMPLE mode only works when CHx_INTERACT_SAMPLE is set to ACMP.

If ADC0 is used, LESENSE will initiate ADC conversions and fetch the ADC data for further evaluation. If the ADC is configured in differential mode, CHx_INTERACT_SAMPLE must be set to ADCDIFF. In this mode, the output from the ADC and the threshold used for comparison are given in two's complement notation.

See sections28.3.12 ADC Interface and 28.3.10 ACMP Interface for more details on the LESENSE interface to the ADC and ACMPs. The sampled data from ADC or ACMP will be referred to as sensor data in the remainder of this manual.

#### 28.3.6 Sensor Evaluation

When a measurement phase is completed, the sensor data is evaluated by the evaluation block. If the sensor data is taken from ACMP sample in a single point in time (CHx_INTERACT_SAMPLE = ACMP), the evaluation is limited to determining if the sensor data is 0 or 1. For the other sample modes, there are three ways to do sensor evaluation; threshold comparison, sliding window, or step detection. Evaluation mode is configured in CHx_EVAL_MODE.

If the evaluation of sensor data evaluates to true, the corresponding bit in the result register (SCANRES) is set. By configuring SETIF in CHx_INTERACT, interrupt flags can also be set on SCANRES events. Figure 28.7 Scan Result and Interrupt Generation on page 961 illustrates how the sensor data or ACMP sample is used for evaluation and interrupt generation.

**Note:** For initialization purposes, SCANRES can be written by software. SCANRES should not be written while LESENSE is running (i.e., the RUNNING bit in LESENSE_STATUS is high).

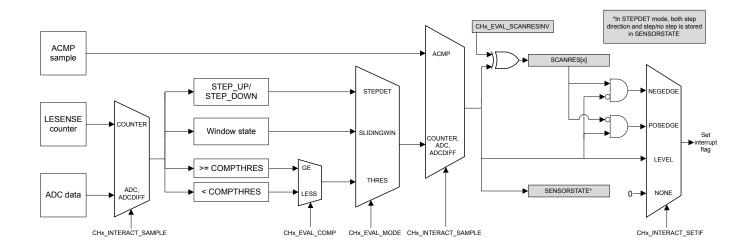

Figure 28.7. Scan Result and Interrupt Generation

The results from sensor data evaluation can be fed into the decoder through the SENSORSTATE register. In DUALSAMPLE mode, results from both the sampled ACMPs will be stored in both SCANRES and SENSORSTATE.

## 28.3.6.1 Threshold Comparison

In threshold comparison mode, the sensor data is compared to a threshold configured in CHx_EVAL_COMPTHRES. There are two modes of threshold comparison: 'less than' and 'greater than or equal'. Threshold comparison mode is configured in CHx_EVAL_COMP.

## 28.3.6.2 Sliding Window

In sliding window mode, the sensor data is compared against the upper and lower limits of a window range. The window is defined by a base, given by CHx_EVAL_COMPTHRES, and a size configured in EVALCTRL_WINSIZE. The window size is constant and the same for all LESENSE channels, while the base is specific to each channel and will be updated by LESENSE when the sensor data is outside the current window range. If the sensor data is within the window range, the sensor evaluation will remain the same as it was for the previous measurement. If the sensor data is below the window range, the measurement will be evaluated to false. If the sensor data is above the window range, the measurement will be evaluated to true. In both cases, the window base in CHx_EVAL_COMPTHRES will be updated to reflect the new window range. Figure 28.8 Sliding Window on page 962 shows how the sliding window evaluation mode can be used to implement a system with two self calibrating thresholds.

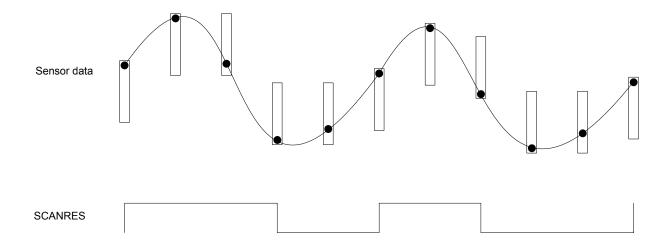

Figure 28.8. Sliding Window

#### 28.3.6.3 Step Detection

Step detection is used to detect steps in the sensor data compared to sensor data from the previous measurement. The size of the step is configured in EVALCTRL_WINSIZE. In this mode, step up and step down are evaluated as described in Figure 28.9 Step Detection on page 962:

STEP_UP = SENSORDATA; >= SENSORDATA;-1 + EVALCTRL_WINSIZE STEP_DOWN = SENSORDATA; < SENSORDATA;-1 - EVALCTRL_WINSIZE

# Figure 28.9. Step Detection

If either a step up or a step down is detected, the SCANRES bit for the active channel will be set. In addition, the STEPDIR bit for the channel will be updated to indicate if a step up or a step down was detected. STEPDIR = 1 indicates a step up. In this mode, previous sensor data is stored in CHx_EVAL_COMPTHRES.

#### 28.3.7 Decoder

Many applications, such as quadrature decoding, require some sort of processing of the sensor readings. In quadrature decoding, the sensors repeatedly pass through a set of states which correspond to the position of the sensors. This sequence, and many other decoding schemes, can be described as a finite state machine. To support this type of decoding without CPU intervention, the LESENSE module includes a highly configurable decoder capable of decoding input from up to four sensors. The decoder is implemented as a programmable state machine with up to 32 states. When doing a sensor scan, the results from the sensors are placed in the decoder input register, SENSORSTATE, if DECODE in CHx_INTERACT is set. The resulting position after a scan is illustrated in Figure 28.10 Sensor Scan and Decode Sequence on page 963, where the bottom blocks show how the SENSORSTATE register is filled. If step detection is enabled, the step direction is placed in SENSORSTATE in the position after the sensor result. When the scan sequence is complete, the decoder evaluates the state of the sensors chosen for decoding, as depicted in Figure 28.10 Sensor Scan and Decode Sequence on page 963.

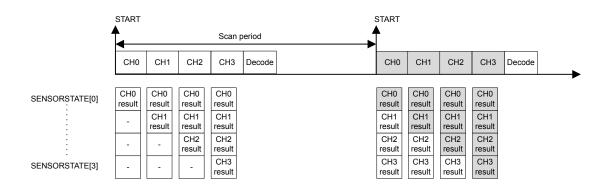

Figure 28.10. Sensor Scan and Decode Sequence

Upon a state transition, LESENSE can generate a pulse on one or more of the decoder PRS channels. Which PRS channel to generate a pulse on is configured in the PRSACT bit field. If PRSCNT in DECCTRL is set, count signals will be generated on decoder PRS channels 0 and 1 according to the PRSACT configuration. In this mode, channel 0 will pulse each time a count event occurs, while channel 1 indicates the count direction (1 being up and 0 being down). The count direction will be kept at its previous state in between count events. The EFR32xG12 Wireless Gecko pulse counter may be used to keep track of events based on these PRS outputs.

If SETIF is set, the DECODER interrupt flag will be set when the transition occurs. If INTMAP in DECCTRL and SETIF is set, a transition from state x or x+16 will set the CHx interrupt flag in addition to the DECODER flag.

Setting CHAIN in STx_TCONFA enables the decoder to evaluate more than two possible transitions for each state. If none of the transitions defined in STx_TCONFA or STx_TCONFB match, the decoder will jump to the next descriptor pair and evaluate the transitions defined there. The decoder uses two LFACLK_{LESENSE} cycles for each descriptor pair to be evaluated. If ERRCHK in CTRL is set, the decoder will check that the sensor state has not changed if none of the defined transitions match. The DECERR interrupt flag will be set if none of the transitions match and the sensor state has changed. Figure 28.11 Decoder State Transition Evaluation on page 964 illustrates state transitions. The "Generate PRS signals and set interrupt flag" blocks will perform actions according to the configuration in STx TCONFA and STx TCONFB.

Note: If only one transition from a state is used, STx TCONFA and STx TCONFB should be configured equally.

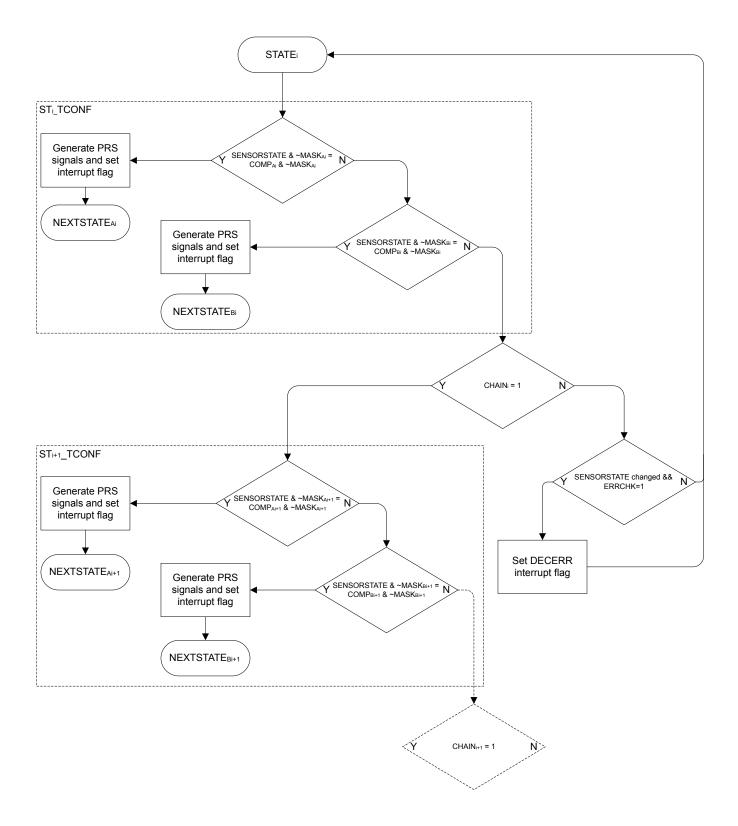

Figure 28.11. Decoder State Transition Evaluation

The DECODER has a PRS output named DECCMP. This output can be used to indicate which state, or subset of states, the decoder is currently in. This PRS output is enabled by setting DECCMPEN in PRSCTRL, and configured through DECCMPMASK and DECCMPV-AL in PRSCTRL. The value of this PRS output is given by Figure 28.12 DECCMP PRS Output on page 965,

PRS_DECCMP = (DECSTATE & ~DECCMPMASK) == (DECCMPVAL & ~DECCMPMASK)

## Figure 28.12. DECCMP PRS Output

To prevent unnecessary interrupt requests or PRS outputs when the decoder toggles back and forth between two states, a hysteresis option is available. The hysteresis function is triggered if a type A transition is preceded by a type B transition, and vice versa. A type A transition is defined in STx_TCONFA, and a type B transition is defined in STx_TCONFB. When descriptor chaining is used, a jump to another descriptor will cancel out the hysteresis effect. Figure 28.13 Decoder Hysteresis on page 965 illustrates how the hysteresis triggers upon state transitions.

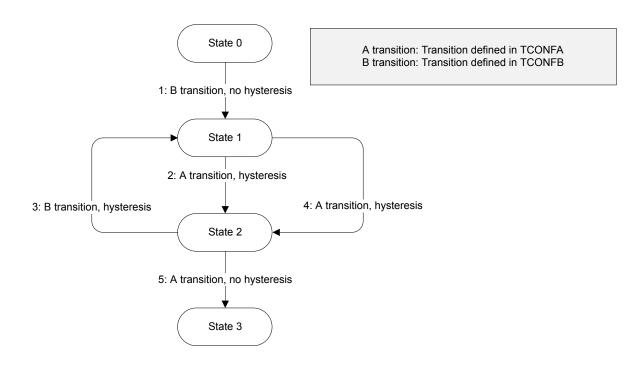

Figure 28.13. Decoder Hysteresis

- When HYSTPRSx is set, PRS signal x is suppressed when the hysteresis triggers.
- When HYSTIRQ is set, interrupt requests are suppressed when the hysteresis triggers.

**Note:** The decoder error interrupt flag, DECERR, is not affected by the hysteresis.

#### 28.3.8 Measurement Results

Part of the LESENSE RAM is treated as a circular buffer for storage of up to 16 sensor measurements results. Each time LESENSE writes data to the result buffer, the result write pointer (PTR_WR) is incremented. Each time a new result is read through the BUFDATA register, the result read pointer (PTR_RD) is incremented. The read pointer will not be incremented if there is no valid, unread data in the result buffer. By default LESENSE will not write additional data to a full result buffer until the data is read by software or DMA. Setting BUFOW in CTRL enables LESENSE to write to the result buffer even if it is full. In this mode, the result read pointer will follow the write pointer if the buffer is full. The result of this is that data read from the result read register (BUFDATA) will be the oldest unread result. The location pointers are available in PTR.

The result buffer has three flags in the STATUS register: BUFDATAV, BUFHALFFULL, and BUFFULL. The flags indicate when new data is available, when the buffer is half full, and when it is full, respectively.

The result buffer also has three interrupt flags in the IR register: BUFDATAV, BUFLEVEL, and BUFOF. BUFDATAV is set when data is available in the buffer. BUFLEVEL is set when the buffer is either full or half-full, depending on the configuration of BUFIDL in CTRL. BUFOF is set if the result buffer overflows.

During a scan, the state of each sensor is stored in SCANRES. If a sensor triggers, a 1 is stored in SCANRES, else a 0 is stored in SCANRES. Whether or not a sensor is said to be triggered depends of the configuration for the given channel. See 28.3.6 Sensor Evaluation for details. If STRSAMPLE in CHx_EVAL is set, the sensor data for each channel will be stored in the LESENSE result buffer. If STRSCANRES in CTRL is set, the result vector, SCANRES, will also be stored in the result buffer. This will be stored after each scan and will be interleaved with the counter values. The contents of the result buffer can be read from BUFDATA or from BUF[x]_DATA. When reading from BUF[x]_DATA, neither the result read pointer or the status flags BUFDATAV, BUFHALFFULL, or BUFFULL will be updated. When reading through the BUFDATA register, the oldest unread result will be read.

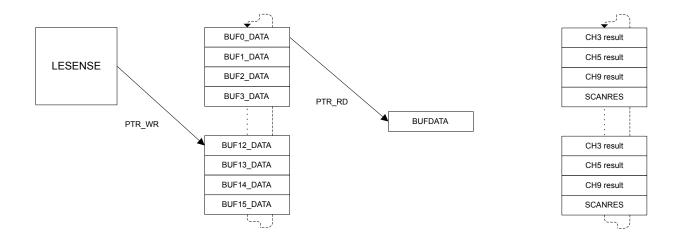

Figure 28.14. Circular Result Buffer

Figure 28.14 Circular Result Buffer on page 966 illustrates how the result buffer would be filled when channels 3,5, and 9 are enabled and have STRSAMPLE in CHx_EVAL set, in addition to STRSCANRES in CTRL. The measurement result from the three channels will be sequentially written during the scan, while SCANRES is written to the result buffer upon scan completion.

#### 28.3.9 VDAC Interface

LESENSE is able to drive the VDAC for generation of accurate reference voltages. This is enabled by setting DACCHxEN in PERCTRL. The refresh rate of the VDAC channels can be configured in DACCONVTRIG in PERCTRL. If DACCONVTRIG is set to CHANNELSTART, the VDAC channels are refreshed prior to each sensor measurement, as depicted in Figure 28.4 Timing Diagram, AUXHFRCO Based Timing on page 957. If DACCONVTRIG is set to SCANSTART, the VDAC channels are refreshed prior to each scan. The conversion data is either taken from the data registers in the EFR32xG12 Wireless Gecko VDAC interface (VDAC0_CH0DATA and VDAC0_CH1DATA) or from the THRES bitfield in the CHx_INTERACT register for the active LESENSE channel. VDAC data used is configured in DACCHxDATA in PERCTRL.

Bias configuration, calibration and reference selection is done in the EFR32xG12 Wireless Gecko VDAC module and LESENSE will not override these configurations.

LESENSE has the possibility to control switches that connect the VDAC alternate outputs. This allows LESENSE to excite sensors with output from the VDAC channels, this is done by setting CHx_INTERACT_EXMODE to DACOUT. The LESENSE channels can also be connected to the VDAC output when the given channel is idle, this is done by setting IDLECONF_CHx to DAC.

**Note:** Only LESENSE channels 4, 5, 7, 10, 12, 13 have the possibility to excite using the VDAC alternate outputs, or connect to the VDAC alternate outputs during the idle phase.

The VDAC may be chosen as reference to the analog comparators for accurate reference generation. If the VDAC is configured in continuous mode this does not require any external components. If sample/off mode is used, an external capacitor is needed to maintain the voltage between samples. To configure the VDAC to use this external capacitor, connect the capacitor to the VDAC pin for the given channel and set SHORT in VDAC_OPAx_OUT.

Note: The VDAC mode should not be altered while DACACTIVE in STATUS is set

#### 28.3.10 ACMP Interface

The analog comparators (ACMPs) are used to measure the sensors, and have to be configured according to the application in order for LESENSE to work properly. Depending on the configuration in the ACMP0MODE and ACMP1MODE bit-fields in PERCTRL, LESENSE will take control of the positive input mux and the voltage dividers (DIVVA, DIVVB) for ACMP0 and ACMP1. The remaining configuration of the analog comparators is done in the ACMP register interface.

If ACMPxMODE in PERCTRL is set to MUX, LESENSE will take control of the positive input mux of the ACMP, through the external override interface, described in the ACMP chapter (see 25.3.12 External Override Interface). The offset given by LESENSE, EXT_OFFSET, depends on whether one or two ACMPs are controlled by LESENSE. If only one ACMP is used, EXT_OFFSET will have the same value as the active channel. If both ACMP0 and ACMP1 are used, LESENSE channel 0-7 will use ACMP0 with EXT_OFFSET_0-7, and LESENSE channel 8-15 will use ACMP1 with EXT_OFFSET_0-7.

If ACMPxMODE in PERCTRL is set to MUXTHRES, LESENSE will also take control of the voltage dividers in the ACMP, DIVVA and DIVVB. The thresholds used are individual to each channel and is configured using the 6 LSBs of CHx_INTERACT_THRES. By default, ACMP_HYSTERESIS0_DIVVX and ACMP_HYSTERESIS1_DIVVX will be given the same value, the 6 LSBs of CHx_INTERACT_THRES. To allow different values for ACMP_HYSTERESIS0_DIVVX and ACMP_HYSTERESIS1_DIVVX, ACMPxHYSTEN in PERCTRL needs to be set. This allows the hysteresis feature in the ACMP to be utilized. ACMP_HYSTERESIS0_DIVVX will get the value programmed in CHx_INTERACT_THRES[5:0], while ACMP_HYSTERESIS1_DIVVX will get the value programmed in CHx_INTERACT_THRES[11:6].

## 28.3.11 ACMP and VDAC Duty Cycling

By default, the analog comparators and the VDAC are shut down between LESENSE scans to save energy. If this is not desired, WAR-MUPMODE in PERCTRL can be configured to prevent them from being shut down.

Both the VDAC and analog comparators rely on a bias module for correct operation. This bias module has a low power mode which consumes less energy at the cost of reduced accuracy. BIASMODE in BIASCTRL configures how the bias module is controlled by LESENSE. When set to DUTYCYCLE, LESENSE will set the bias module in high accuracy mode whenever LESENSE is active, and keep it in the low power mode otherwise. When BIASMODE is set to HIGHACC, the high accuracy mode is always selected. When set to DONTTOUCH, LESENSE will not control the bias module.

#### 28.3.12 ADC Interface

The LESENSE module can be configured to trigger conversions on ADC0 and use data from ADC0 to evaluate sensor status. In order to do this, the scan mode of the ADC has to be configured. When the sample delay configured in CHx_TIMING_SAMPLEDLY has expired, LESENSE will initiate an ADC sample. The active LESENSE channel determines which ADC0 channel to be sampled, where LESENSE channel X corresponds to ADC0 scan channel X.

#### 28.3.13 DMA Requests

LESENSE issues a DMA request when the result buffer is either full or half full, depending on the configuration of BUFIDL in CTRL. The request is cleared when the buffer level drops below the threshold defined in BUFIDL. A single DMA request is also set whenever there is unread data in the buffer. DMAWU in CTRL configures at which buffer level LESENSE should wake-up the DMA when in EM2.

Note: The DMA controller should always fetch data from the BUFDATA register.

## 28.3.14 PRS Output

LESENSE is an asynchronous PRS producer and has twenty PRS outputs. The decoder has four outputs and in addition, all bits in the SCANRES register are available as PRS outputs. For further information on the decoder PRS output, refer to 28.3.7 Decoder.

## 28.3.15 RAM

LESENSE includes a RAM block used for storage of configuration and results. Registers mapped to the RAM include: STx_TCONFA, STx_TCONFB, BUFx_DATA, BUFDATA, CHx_TIMING, CHx_INTERACT, and CHx_EVAL. These registers have unknown value out of reset and have to be initialized before use.

Note: Read-modify-write operations on uninitialized RAM register produces undefined values.

## 28.3.16 Application Examples

The following sections detail several example applications for the LESENSE block.

#### 28.3.16.1 Capacitive Sense

Figure 28.15 Capacitive Sense Setup on page 969 illustrates how the EFR32xG12 Wireless Gecko can be configured to monitor four capacitive buttons.

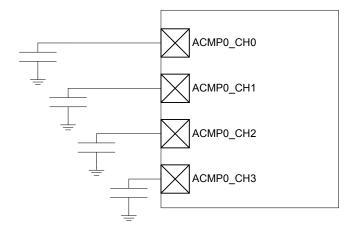

Figure 28.15. Capacitive Sense Setup

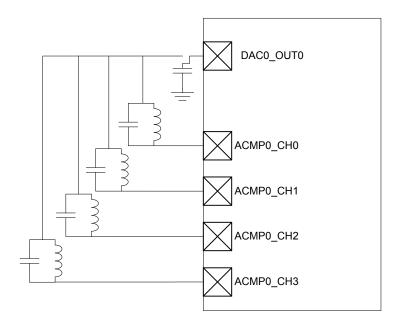

The following steps show how to configure LESENSE to scan through the four buttons 100 times per second, issuing an interrupt if one of them is pressed.

- 1. Assuming LFACLK_{LESENSE} is 32 kHz, set PCPRESC to 3 and PCTOP to 39 in CTRL. This will set the LESENSE scan frequency to 100 Hz.
- 2. Enable channels 0 through 3 in CHEN and set IDLECONF for these channels to DISABLED. In capacitive sense mode, the GPIO should always be disabled (i.e., analog input).
- 3. Configure the ACMP to operate in CAPSENSE mode (refer to the ACMP chapter for more details).
- 4. Configure the following bit fields in CHx CONF, for channels 0 through 3:
  - a. Set EXTIME to 0. No excitation is needed in this mode.
  - b. Set SAMPLE to ACMPCOUNT and COMP to LESS. This makes LESENSE interpret a sensor as active if the frequency on a channel drops below the threshold (i.e., the button is pressed).
  - c. Set SAMPLEDLY to an appropriate value each sensor will be measured for SAMPLEDLY/F_{LFACLK_LESENSE} seconds. MEAS-UREDLY should be set to 0
- 5. Set CTRTHRESHOLD to an appropriate value. An interrupt will be issued if the counter value for a sensor is below this threshold after the measurement phase.
- 6. Enable interrupts on channels 0 through 3.
- 7. Start scan sequence by writing a 1 to START in CMD.

In a capacitive sense application, it might be required to calibrate the threshold values on a periodic basis, for example to compensate for humidity and other physical variations. LESENSE is able to store up to 16 counter values from a configurable number of channels, making it possible to collect sample data while in EM2. When calibration is to be performed, the CPU only has to be woken up for a short period of time as the data to be processed already lies in the result registers. To enable storing of the count value for a channel, set STRSAMPLE in the CHx INTERACT register.

#### 28.3.16.2 LC Sensor

Figure 28.16 LC Sensor Setup on page 970 below illustrates how the EFR32xG12 Wireless Gecko can be set up to monitor four LC sensors.

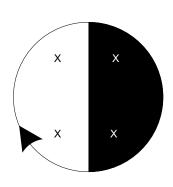

Figure 28.16. LC Sensor Setup

LESENSE can be used to excite and measure the damping factor in LC sensor oscillations. To measure the damping factor, the ACMP can be used to generate a high output each time the sensor voltage exceeds a certain level. These pulses are counted using an asynchronous counter and compared with the threshold in COMPTHRES in the CHx_EVAL register. If the number of pulses exceeds the threshold level, the sensor is said to be active, otherwise it is inactive. Figure 28.17 LC Sensor Oscillations on page 970 illustrates how the output pulses from the ACMP correspond to damping of the oscillations. The results from sensor evaluation can automatically be fed into the decoder in order to keep track of rotations.

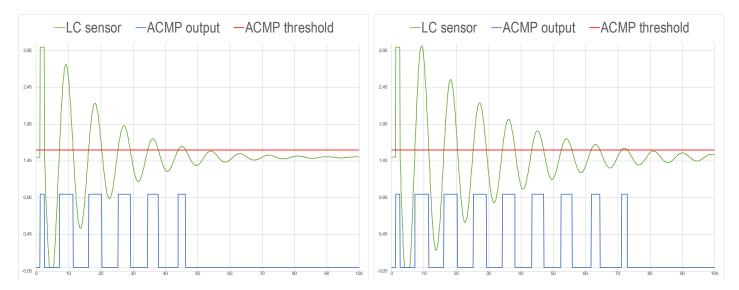

Figure 28.17. LC Sensor Oscillations

The following steps show how to configure LESENSE to scan through the four LC sensors 100 times per second.

- 1. Assuming LFACLK_{LESENSE} is 32kHz, set PCPRESC to 3 and PCTOP to 39 in CTRL. This will set the LESENSE scan frequency to 100Hz.
- 2. Enable the VDAC and configure it to produce a voltage of Vdd/2.

- 3. Enable channels 0 through 3 in CHEN. Set IDLECONF for the active channels to DACOUT. The channel pins should be connected to the VDAC output (effectively shorting the LC sensor) in the idle phase to damp the oscillations.
- 4. Configure the ACMP to use scaled Vdd as negative input, refer to ACMP chapter for details.
- 5. Enable and configure PCNT and asynchronous PRS.
- 6. Configure the GPIOs used as PUSHPULL.
- 7. Configure the following bit fields in CHx CONF, for channels 0 through 3:
  - a. Set EXCLK to AUXHFRCO. AUXHFRCO is needed to achieve short excitation time.
  - b. Set EXTIME to an appropriate value. Excitation will last for EXTIME/F_{AUXHFRCO} seconds.
  - c. Set EXMODE to HIGH. The LC sensors are excited by pulling the excitation pin high.
  - d. Set SAMPLE to ACMPCOUNT and COMP to LESS. Status of each sensor is evaluated based on the number of pulses generated by the ACMP. If they are less than the threshold value, the sensor is said to be active.
  - e. Set SAMPLEDLY to an appropriate value, each sensor will be measured for SAMPLEDLY/F_{LFACLK} LESENSE seconds.
- 8. Set CTRTHRESHOLD to an appropriate value. If the sensor is active, the counter value after the measurement phase should be less than the threshold. If it is inactive, the counter value should be greater than the threshold.
- 9. Start scan sequence by writing a 1 to START in CMD.

**Note:** Exciting the LC sensor by pulling the excitation pin high allows the ESD protection in the pads to clamp any voltage swings below the ground voltage, giving a consistent starting point for the oscillations.

#### 28.3.16.3 LESENSE Decoder 1

The example below illustrates how the LESENSE module can be used for decoding using three sensors.

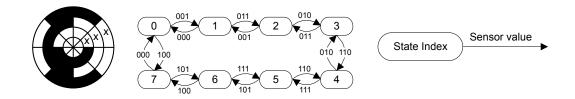

Figure 28.18. FSM Example 1

Figure 28.18 FSM Example 1 on page 972, configure the following LESENSE registers:

- 1. Configure the channels to be used, be sure to set DECODE in CHx EVAL.
- 2. Set PRSCNT to enable generation of count waveforms on PRS. Also configure a PCNT to listen to the PRS channels and count accordingly.
- 3. Configure the following in STx TCONFA and STx TCONFB:
  - a. Set MASK = 0b1000 in STx_TCONFA and STx_TCONFB for all used states. This enables three sensors to be evaluated by the decoder.
  - b. Configure the remaining bit fields in STx_TCONFA and STx_TCONFB as described in Table 28.3 LESENSE Decoder Configuration for FSM Example 1 on page 972.
- 4. To initialize the decoder, run one scan, and read the present sensor status from SENSORSTATE. Then write the index of this state to DECSTATE.
- 5. Write to START in CMD to start scanning of sensors and decoding.

Table 28.3. LESENSE Decoder Configuration for FSM Example 1

Register	TCONFA_ NEXTSTATE	TCONFA_COMP	TCONFA_ PRSACT	TCONFB_ NEXTSTATE	TCONFB_COMP	TCONFB_ PRSACT

#### 28.3.16.4 LESENSE Decoder 2

The example below illustrates how the LESENSE decoder can be used to implement the state machine seen in Figure 28.19 FSM Example 2 on page 973.

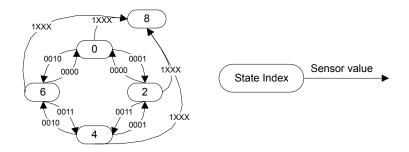

Figure 28.19. FSM Example 2

- 1. Configure STx_TCONFA and STx_TCONFB as described in Table 28.4 LESENSE Decoder Configuration for FSM Example 2 on page 973.
- 2. To initialize the decoder, run one scan, and read the present sensor status from SENSORSTATE. Then write the index of this state to DECSTATE.
- 3. Write to START in CMD to start scanning of sensors and decoding.

Bit	Name	Reset	Access	Description
31:23	Reserved	To ensure co	ompatibility (	with future devices, always write bits to 0. More information in 1.2 Conven-
22	DEBUGRUN	0	RW	Debug Mode Run Enable
	Set to keep LESEN	SE running in de	bug mode.	
	Value			Description
	0			LESENSE can not start new scans in debug mode
	1			LESENSE can start new scans in debug mode
21:20	DMAWU	0x0	RW	DMA Wake-up From EM2
	Set buffer threshold	for waking up th	e DMA conf	troller when the system is in EM2
	Value	Mode		Description
	0	DISABLE		No DMA wake-up from EM2
	1	BUFDATAV		DMA wake-up from EM2 when data is valid in the result buffer
	2	BUFLEVEL		DMA wake-up from EM2 when the result buffer is full/half-full depending on BUFIDL configuration
19	BUFIDL	0	RW	Result Buffer Interrupt and DMA Trigger Level
	Set buffer threshold	for DMA reques	ts and inter	rupt generation
	Value	Mode		Description
	0	HALFFULL		DMA and interrupt flags set when result buffer is half-full
	1	FULL		DMA and interrupt flags set when result buffer is full
18	Reserved	To ensure co	ompatibility (	with future devices, always write bits to 0. More information in 1.2 Conven-
17	STRSCANRES	0	RW	Enable Storing of SCANRES
	When set, SCANRE	S will be stored	in the result	buffer after each scan

Bit	Name	Reset	Access	Description
16	BUFOW	0	RW	Result Buffer Overwrite
	If set, LESENSE wil	l always write to	the result b	uffer, even if it is full
15:14	Reserved	To ensure co	mpatibility v	with future devices, always write bits to 0. More information in 1.2 Conven-
13	DUALSAMPLE	0	RW	Enable Dual Sample Mode
	When set, both ACM	VIPs will be samp	led simultar	neously.
12	Reserved	To ensure co	mpatibility v	with future devices, always write bits to 0. More information in 1.2 Conven-
11	ALTEXMAP	0	RW	Alternative Excitation Map
	This bit is used to co	onfigure which pi	ns alternate	e excitation is mapped to.
	Value	Mode		Description
	0	ALTEX		Alternative excitation is mapped to the LES_ALTEX pins.
	1	СН		Alternative excitation is mapped to the pin of LESENSE channel (X+8 mod 16), X being the active channel.
10:9	Reserved	To ensure co	mpatibility v	with future devices, always write bits to 0. More information in 1.2 Conven-
8:7	SCANCONF	0x0	RW	Select Scan Configuration
	These bits control w	hich CHx_CONF	registers to	o be used.
	Value	Mode		Description
	0	DIRMAP		The channel configuration register registers used are directly mapped to the channel number.
	1	INVMAP		The channel configuration register registers used are $CH_{X+8}$ _CONF for channels 0-7 and $CH_{X-8}$ _CONF for channels 8-15.
	2	TOGGLE		The channel configuration register registers used toggles between $CH_{X}$ _CONF and $CH_{X+8}$ _CONF when channel x triggers
	3	DECDEF		The decoder state defines the CONF registers to be used.
6	Reserved	To ensure co	mpatibility v	with future devices, always write bits to 0. More information in 1.2 Conven-
5:2	PRSSEL	0x0	RW	Scan Start PRS Select
	Select PRS source	for scan start if S	CANMODE	is set to PRS.
	Value	Mode		Description
	0	PRSCH0		PRS Channel 0 selected as input
	1	PRSCH1		PRS Channel 1 selected as input
	2	PRSCH2		PRS Channel 2 selected as input
	3	PRSCH3		PRS Channel 3 selected as input
	4	PRSCH4		PRS Channel 4 selected as input
	5	PRSCH5		PRS Channel 5 selected as input
	6	PRSCH6		PRS Channel 6 selected as input
	7	PRSCH7		PRS Channel 7 selected as input

Name	Reset	Access	Description
8	PRSCH8		PRS Channel 8 selected as input
9	PRSCH9		PRS Channel 9 selected as input
10	PRSCH10		PRS Channel 10 selected as input
11	PRSCH11		PRS Channel 11 selected as input
SCANMOD	DE 0x0	RW	Configure Scan Mode
These bits	control how the scan frequ	ency is de	cided
Value	Mode		Description
0	PERIODIC		A new scan is started each time the period counter overflows
1	ONESHOT		A single scan is performed when START in CMD is set
2	PRS		Pulse on PRS channel
2	FNO		1 disc of 1 10 chamic

# 28.5.2 LESENSE_TIMCTRL - Timing Control Register (Async Reg)

8	INPUT	0 RW	LESENSE Decoder Input Configuration
	Select input to the	LESENSE decoder	
	Value	Mode	Description
	0	SENSORSTATE	The SENSORSTATE register is used as input to the decoder.
	1	PRS	PRS channels are used as input to the decoder.
7	PRSCNT	0 RW	Enable Count Mode on Decoder PRS Channels 0 and 1
	When set, decode	er PRS0 and PRS1 will be	used to produce output which can be used by a PCNT to count up or down.
6	HYSTIRQ	0 RW	Enable Decoder Hysteresis on Interrupt Requests
	When set, hystere	esis is enabled in the deco	oder, suppressing interrupt requests.
5	HYSTPRS2	0 RW	Enable Decoder Hysteresis on PRS2 Output
	When set, hystere	esis is enabled in the deco	oder, suppressing changes on PRS channel 2
4	HYSTPRS1	0 RW	Enable Decoder Hysteresis on PRS1 Output
	When set, hystere	esis is enabled in the deco	oder, suppressing changes on PRS channel 1
3	HYSTPRS0	0 RW	Enable Decoder Hysteresis on PRS0 Output
	When set, hystere	esis is enabled in the deco	oder, suppressing changes on PRS channel 0
2	INTMAP	0 RW	Enable Decoder to Channel Interrupt Mapping
	When set, a transi	ition from state x in the de	ecoder will set interrupt flag CH[x mod 16]
1	ERRCHK	0 RW	Enable Check of Current State
	When set, the dec	coder checks the current	state in addition to the states defined in TCONF
0	DISABLE	0 RW	Disable the Decoder
	When set, the dec	coder is disabled. When c	isabled the decoder will keep its current state

### 29. GPCRC - General Purpose Cyclic Redundancy Check

#### **Quick Facts**

#### What?

The GPCRC is an error-detecting module commonly used in digital networks and storage systems to detect accidental changes to data.

#### Why?

The GPCRC module can detect errors in data, giving a higher system reliability and robustness.

#### How?

Blocks of data entering GPCRC module can have a short checksum, based on the remainder of a polynomial division of their contents; on retrieval the calculation is repeated, and corrective action can be taken against presumed data corruption if the check values do not match.

#### 29.1 Introduction

The GPCRC module is a slave peripheral that implements a Cyclic Redundancy Check (CRC) function. It supports both 32-bit and 16-bit polynomials. The supported 32-bit polynomial is 0x04C11DB7(IEEE 802.3), while the 16-bit polynomial can be programmed to any value, depending on the needs of the application. Common 16-bit polynomials are 0x1021 (CCITT-16), 0x3D65 (IEC16-MBus), and 0x8005 (zigbee, 802.15.4, and USB).

#### 29.2 Features

- Programmable 16-bit polynomial, fixed 32-bit polynomial
- Byte-level bit reversal for the CRC input
- Byte-order reorientation for the CRC input
- · Word or half-word bit reversal of the CRC result
- · Ability to configure and seed an operation in a single register write
- · Single-cycle CRC computation for 32-, 16-, or 8-bit blocks
- · DMA operation

### 29.3 Functional Description

An overview of the GPCRC module is shown in Figure 29.1 GPCRC Overview on page 1022.

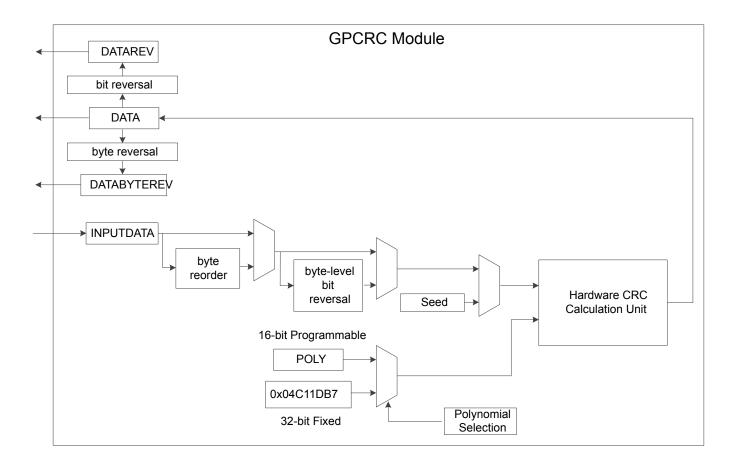

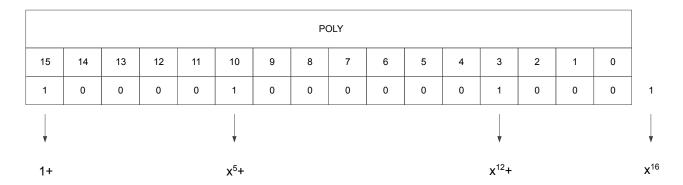

Figure 29.1. GPCRC Overview

#### 29.3.1 Polynomial Specification

POLYSEL in GPCRC_CTRL selects between 32-bit and 16-bit polynomial functions. When a 32-bit polynomial is selected, the fixed IEEE 802.3 polynomial(0x04C11DB7) is used. When a 16-bit polynomial is selected, any valid polynomial can be defined by the user in GPCRC_POLY.

A valid 16-bit CRC polynomial must have an  $x^{0}$  term and an  $x^{0}$  term. Theoretically, a 16-bit polynomial has 17 terms total. The convention used is to omit the  $x^{0}$  term. The polynomial should be written in **reversed** (little endian) bit order. The most significant bit corresponds to the lowest order term. Thus, the most significant bit in CRC_POLY represents the  $x^{0}$  term, and the least significant bit in CRC_POLY represents the  $x^{1}$  term. The highest significant bit of CRC_POLY should always set to 1. The polynomial representation for the CRC-16-CCIT polynomial  $x^{1}$  +  

CRC-16-CCITT Normal: 0x1021 Reversed: 0x8408

Figure 29.2. Polynomial Representation

#### 29.3.2 Input and Output Specification

The CRC input data can be written to the GPCRC_INPUTDATA, GPCRC_INPUTDATAHWORD or GPCRC_INPUTDATABYTE register via the APB bus based on different data size. If BYTEMODE in GPCRC_CTRL is set, only the least significant byte of the data word will be used for the CRC calculation no matter which input register is written. There are also three output registers for different ordering. Reading from GPCRC_DATA will get the result based on the polynomial in reversed order, while reading from GPCRC_DATAREV will get the result based on the polynomial in normal order. The CRC calculation needs one clock cycle, reading from GPCRC_DATA, GPCRC_DATAREV or GPCRC_DATABYTEREV register or writting to GPCRC_CMD register is halted while the calculation is in progress.

#### 29.3.3 Initialization

The CRC can be pre-loaded or re-initialized by first writing a 32-bit programmable init value to INIT in GPCRC_INIT and then setting INIT in GPCRC_CMD. It can also be re-initialized automatically when read from DATA, DATAREV or DATABYTEREV provided that AUTOINIT in GPCRC_CTRL is set, the CRC would be re-initialized with the stored init value.

#### 29.3.4 DMA Usage

A DMA channel may be used to transfer data into the CRC engine. All bytes and half-word writes must be word-aligned. The recommended DMA usage model is to use the DMA to transfer all avaliable words of data and use software writes to capture any remaining bytes.

### 29.3.5 Byte-Level Bit Reversal and Byte Reordering

The byte-level bit reversal and byte reordering operations occur before the data is used in the CRC calculation. Byte reordering can occur on words or half words. The hardware ignores the BYTEREVERSE field with any byte writes or operations with byte mode enabled (BYTEMODE = 1), but the bit reversal settings (BITREVERSE) are still applied to the byte. 32-bit little endian MSB-first data can be treated like 32-bit little endian LSB-first data, as shown in Figure 29.3 Data Ordering Example - 32-bit MSB -first to LSB-first on page 1024. In this example, 32-bit data is written to GPCRC_INPUTDATA, BYTEREVERSE is set for byte ordering, and BITREVERSE is set for byte-level bit reversal.

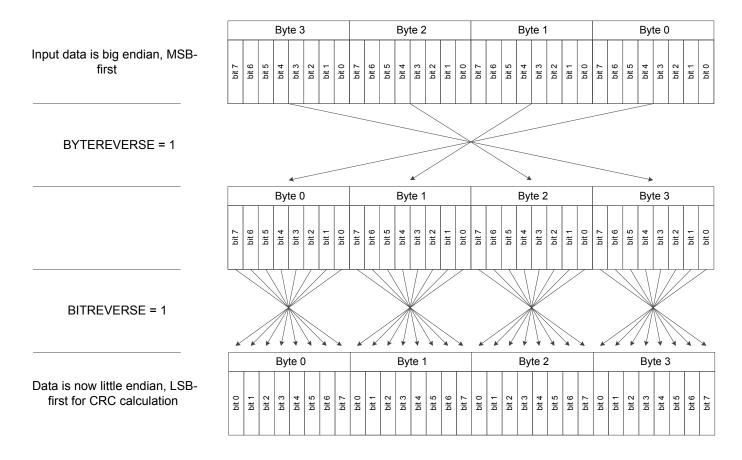

Figure 29.3. Data Ordering Example - 32-bit MSB -first to LSB-first

When handling 16-bit data, the byte reordering function only swap the two lowest bytes and clear the two highest bytes, as shown in Figure 29.4 Data Ordering Example - 16-bit MSB -first to LSB-first on page 1025. In this example, 16-bit data is written to GPCRC_IN-PUTDATAHWORD, BYTEREVERSE is set for byte ordering, and BITREVERSE is set for byte-level bit reversal.

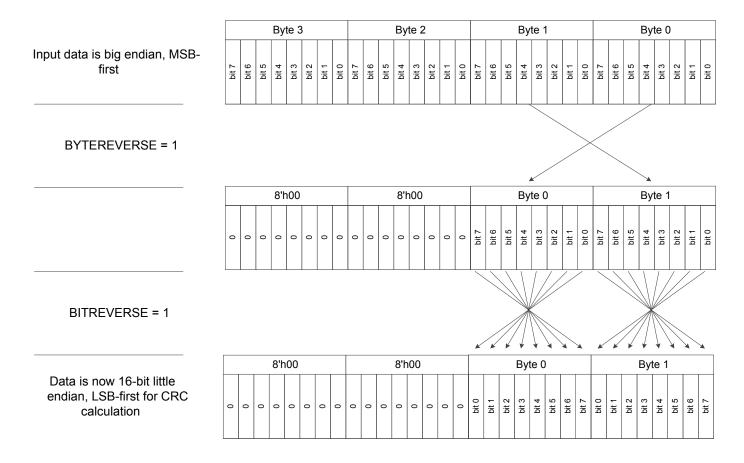

Figure 29.4. Data Ordering Example - 16-bit MSB -first to LSB-first

Assuming a word input byte order of B3 B2 B1 B0, the values used in the CRC calculation for the various settings of the byte-level bit reversal and byte reordering are shown in Table 29.1 Byte-Level Bit Reversal and Byte Reordering Results (B3 B2 B1 B0 Input Order) on page 1025.

Table 29.1. Byte-Level Bit Reversal and Byte Reordering Results (B3 B2 B1 B0 Input Order)

Input Width(bits)	BYTEREVERSE Setting	BITREVERSE Setting	Input to CRC Calculation
32	0	0	B3 B2 B1 B0
32	1	1	'B0 'B1 'B2 'B3
32	1	0	B0 B1 B2 B3
32	0	1	'B3 'B2 'B1 'B0
16	0	0	XX XX B1 B0
16	1	1	XX XX 'B0 'B1
16	1	0	XX XX B0 B1
16	0	1	XX XX 'B1 'B0
8	-	0	XX XX XX XX B0
8	-	1	XX XX XX XX 'B0

Input Width(bits)	BYTEREVERSE Setting	BITREVERSE Setting	Input to CRC Calculation
Note:			
1. X indicates a "don't	care".		
2. Bn is the byte field	within the word.		
3. 'Bn is the bit-revers	ed byte field within the word.

31:16	Reserved	To ensure co tions	mpatibility (	with future devices, always write bits to 0. More information in 1.2 Conven-
15:0	POLY	0x0000	RW	CRC Polynomial Value

This value defines 16-bit POLY, which is used as the polynomial during the 16-bit CRC calculation. The polynomial is defined in reversed representation, meaning that the lowest degree term is in the highest bit position of POLY. Additionally, the highest degree term in the polynomial is implicit. Further examples of the CRC configuration can be found in the documentation.

Bit	Name	Reset	Access	Description
31:0	DATABYTEREV	0x00000000	R	Data Byte Reverse Value

Byte reversed version of CRC Data register. When a 32-bit CRC polynomial is selected, the bytes are swizzled to {B0, B1, B2, B3}. When a 16-bit CRC polynomial is selected, the bytes are swizzled to {0, 0, B0, B1}.

#### 30. TRNG - True Random Number Generator

#### **Quick Facts**

#### What?

The TRNG module is a non-deterministic random number generator based on a full hardware solution.

#### Why?

Secure cryptography commonly relies on randomlygenerated numbers for key generation. Software solutions for random number generation do not usually produce results with enough entropy to satisfy existing standards. Dedicated hardware can provide suitable entropy in an energy-efficient, non-intrusive manner, while also relieving software burden.

#### How?

Ring oscillators and sampling logic combine to produce non-deterministic random numbers.

#### 30.1 Introduction

The TRNG module is a non-deterministic random number generator based on a full hardware solution. The TRNG output passes the NIST 800-22 and AIS31 test suites.

#### 30.2 Features

- · Simple bus interface to access random numbers, control, and status registers
- · 64 x 32-bit FIFO for random number access
- · Interrupt sources from different FIFO, error, and noise alarm events
- Passes NIST 800-22 and AIS31
- · Ready for NIST 800-90B
- · Health tests compliant to NIST 800-90B and AIS31

#### 30.3 Functional Description

Software drivers provided by Silicon Labs offer a simple API interface to the TRNG module. It is highly recommended to use the provided software librariesto access the TRNG module. An overview of the TRNG module is shown in Figure 30.1 TRNG Overview on page 1034.

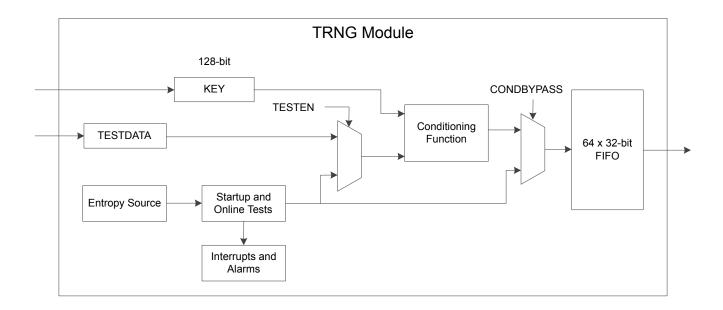

Figure 30.1. TRNG Overview

#### 30.3.1 Built-In Tests

The TRNG module includes several built-in tests to detect issues with the noise source, ensure entropy, and meet cryptography standards. The Repetition Count Test and Adaptive Proportion Test with window sizes of 64 and 4096 bits described in section 6.5.1.2 of NIST-800-90B (http://csrc.nist.gov/publications/drafts/800-90/draft-sp800-90b.pdf) are implemented in hardware and run continuously on the data. All three tests have corresponding interrupt flags that can optionally be used to generate a system interrupt.

The AIS31 Online Test described in section 5.5.3 of https://www.bsi.bund.de/SharedDocs/Downloads/DE/BSI/Zertifizierung/Interpretationen/AIS_31_Functionality_classes_for_random_number_generators_e.pdf is also implemented in hardware, and runs continuously on the data. Both the preliminary noise alarm and the noise alarm are optionally available as interrupt sources from the TRNG module. If a noise alarm occurs, the TRNG will be shut down, and must be reset with a software reset.

Additionally, the NIST-800-90B and AIS31 startup tests may be optionally enabled or disabled by software. The NIST-800-90B startup test is enabled if the CONTROL_BYPNIST bit is cleared to 0. The AIS31 startup test is likewise enabled when CONTROL_BYPAIS31 is cleared to 0. If either the NIST-800-90B or AIS31 startup tests are enabled, no data will be written to the output FIFO until the startup requirements for these tests pass.

#### 30.3.2 FIFO Interface

The TRNG module includes a 64-word output FIFO to hold the output data as it becomes available. The number of 32-bit words available in the FIFO may be checked at any time by reading the FIFOLEVEL register. When the FIFO is completely filled, the TRNG will be shut down, the STATUS_FULLIF flag will be set, and no further data will be written to the FIFO until the FIFO has been flushed. Data may be read from the FIFO one word (32-bits) at a time via the FIFO register. The STATUS_FULLIF flag is cleared upon reading the FIFOLEVEL register.

### 30.3.3 Data Format - Byte Ordering

All cryptographic data is handled following the big-endian format (AES standard). The first byte (lowest address) of the data is the Most Significant Byte (MSB). However, the bus interfaces on the core use little endian format for internal byte ordering within a 32-bit word. The Least Significant Byte (LSB) within a word is stored at the lowest address.

For example, a 128-bit block 0x00112233445566778899AABBCCDDEEFF is read from the FIFO in the following order:

Word 1 = 0x33221100

Word 2 = 0x77665544

Word 3 = 0xBBAA9988

Word 4 = 0xFFDDEECC

This is important to note when checking the conditioning function for validity. The KEY registers also follow this standard, with KEY0 holding the MSB of a 128-bit value and KEY3 holding the LSB.

#### 30.3.4 TRNG Usage

It is highly recommended to use the software libraries provided by Silicon Labs to access the TRNG module. The information in the following sections are reference for users who choose to write their own low-level software drivers.

### 30.3.4.1 Checking the Conditioning Function

The conditioning function receives 512 bits from the entropy source and generates 128 bits of output. The conditioning function can be tested by writing a known key and known data into the block with test mode enabled, then validating against the expected output. The sequence of operations to test the conditioning function is as follows:

- 1. Apply a software reset by setting CONTROL SOFTRESET to 1, then clearing it to 0.
- 2. Configure the CONTROL register. Important configuration options include:
  - Enable test mode by setting CONTROL_TESTEN to 1.
  - Ensure the conditioning function is used by clearning CONTROL_CONDBYPASS to 0.
- 3. Write the key into registers KEY0, KEY1, KEY2, and KEY3.
- 4. Write the 512 bits of known data to TESTDATA 32 bits at a time, polling for STATUS_TESTDATABUSY = 0 after each write.
- 5. Read the 128-bit result from the FIFO 32 bits at a time.

Table 30.1 Known-Answer Test for Conditioning Function on page 1036 shows an example with a given key, known data input, and expected output (taken from section F.2.1 in http://csrc.nist.gov/publications/nistpubs/800-38a/sp800-38a.pdf).

Table 30.1. Known-Answer Test for Conditioning Function

	128-bit Format	32-bit Bus Format
Key	0x2B7E151628AED2A6ABF7158809CF4F3C	0x16157E2B 0xA6D2AE28 0x8815F7AB 0x3C4FCF09
Input	0x6BC0BCE12A459991E134741A7F9E1925	0xE1BCC06B 0x9199452A 0x1A7434E1 0x25199E7F

	0xF69F2445DF4F9B17AD2B417BE66C3710	0x45249FF6 0x179B4FDF 0x7B412BAD 0x10376CE6
Expected output	0x3FF1CAA1681FAC09120ECA307586E1A7	0xA1CAF13F 0x09AC1F68 0x30CA0E12 0xA7E18675

#### 30.3.4.2 Checking the Entropy Source

The entropy source may be checked using the three built in test sources: repetition count, 64-sample adaptive proportion, and 4096-sample adaptive proportion. The entropy source may be tested using the following sequence:

- 1. Apply a software reset by setting CONTROL SOFTRESET to 1, then clearing it to 0.
- 2. Configure the CONTROL register. Important configuration options include:
  - Disable test mode by clearing CONTROL TESTEN to 0.
  - Bypass the conditioning function by setting CONTROL CONDBYPASS to 1.
  - Enable the TRNG by setting CONTROL_ENABLE to 1.
- 3. Check the FIFOLEVEL register to monitor the amount of generated random numbers or wait for the STATUS_FULLIF flag to set, indicating the FIFO is full. Note that STATUS_FULLIF may be configured to generate an interrupt if desired.
- 4. When FIFOLEVEL has reached the expected value or when STATUS_FULLIF is set, read the random numbers using the FIFO register. Those values can be discarded.
- 5. Continue reading and discarding the random data until at least 4097 x 2 bits (257 x 32-bit words) have been read. This ensures that enough time has passed for the longest test to run.
- 6. Check the STATUS register for error flags.

#### 30.3.4.3 Programming a Random Key

- 1. Check the FIFOLEVEL register to monitor the amount of generated random numbers or wait for the STATUS_FULLIF flag to set, indicating the FIFO is full. Note that STATUS_FULLIF may be configured to generate an interrupt if desired.
- 2. When FIFOLEVEL has reached the expected value or when STATUS_FULLIF is set, read the random numbers using the FIFO register.
- Use four 32-bit random values to program a random key to the KEY0, KEY1, KEY2, and KEY3 registers.
- 4. Apply a software reset by setting CONTROL_SOFTRESET to 1, then clearing it to 0. This will flush the FIFO data.

#### 30.3.4.4 Reading Samples

- Check the FIFOLEVEL register to monitor the amount of generated random numbers or wait for the STATUS_FULLIF flag to set, indicating the FIFO is full. Note that STATUS_FULLIF may be configured to generate an interrupt if desired.
- When FIFOLEVEL has reached the expected value or when STATUS_FULLIF is set, read the random numbers using the FIFO register.

### 30.4 Register Map

The offset register address is relative to the registers base address.

## 31. CRYPTO - Crypto Accelerator

#### **Quick Facts**

### What?

A fast and energy efficient autonomous hardware accelerator for AES encryption and decryption with 128- or 256-bit keys, ECC over prime and binary Galois finite fields, SHA-1, SHA-224 and SHA-256.

### Why?

Efficient cryptography with little or no CPU intervention helps to meet the speed and energy demands of the application. Hardware implementations are generally more secure against side-channel attacks than software implementations.

#### How?

Programmable sequences of instructions on big numbers allow fast processing with little CPU intervention. Furthermore, CRYPTO is linked to the Buffer Controller (BUFC), thus enabling fast and efficient autonomous cipher operations on data buffer content.

## 31.1 Introduction

The CRYPTO module allows efficient acceleration of common cryptographic operations and allows these to be used efficiently with a low CPU load. Operations performed by CRYPTO can be set up as a sequence of instructions on a set of 128-bit, 256-bit or 512-bit registers to implement or accelerate Elliptic Curve Cryptography (ECC), SHA-1, SHA-224, SHA-256, and various block cipher modes based on the Advanced Encryption Standard, also known as AES (FIPS-197).

CRYPTO is capable of autonomously fetching data, performing cipher operations and storing data across multiple blocks. When the source data is not a multiple of 16 bytes (128 bits), Zero-padding can be included in the last block. Block operations such as Counter Mode (CTR), Electronic Code Book (ECB), Cipher Block Chaining (CBC), Cipher Feedback (CFB) and Output Feedback (OFB) are easily implemented. Block Cipher modes of operation such as Electronic Code Book (ECB), Counter Mode (CTR), Cipher Block Chaining (CBC), CBC-MAC (CBC Message Authentication Code), CCM (Counter with CBC-MAC) and GCM (Galois Counter mode) are easily implemented.

CRYPTO is delivered with an extensive software library in Simplicity Studio that implements all major cryptographic algorithms, including but not limited to AES, SHA-1, SHA-2, ECC, and legacy algorithms DES, 3DES, MD4, MD5 and RC4. The implementation accelerates the algorithms using CRYPTO when possible.

#### 31.2 Features

- · Efficient AES core
  - Encryption/decryption using 128-bit key (54 clock cycles) or 256-bit key (75 clock cycles)
  - · Key buffer
  - Supports autonomous cipher block modes (e.g. ECB, CTR, CBC, PCBC, CFB, CBC-MAC, GMAC, CCM, CCM* and GCM) across multiple blocks
- Accelerated SHA-1, SHA-224 and SHA-256
- Accelerated Elliptic Curve Cryptography (ECC)
  - · Binary and Prime fields
  - Supports NIST recommended curves: P-192, P-224, P-256, K-163, K-233, B-163, and B-233
- Galois/Counter Mode (GCM)
  - · ALU operations on GCM GF(2^128) field
- · Flexible 256-bit ALU and sequencer
  - 5 general purpose 256-bit registers
  - · Supports ADD, SUB, MUL, shift, XOR, etc.
  - · Up to 20 instructions can be chained to implement various block cipher modes
- · Efficient operation
  - Automatic data loading and storing from registers (through BUFC, the buffer controller)
  - · DMA request signals for data read and write
  - · Optional XOR Data write
  - · Interrupt on finished operations
- · Extensive software support
  - · Extensive software library in Simplicity Studio
  - · Implements all major cryptographic algorithms: AES, SHA-1, SHA-2, and ECC
  - · Implements legacy algorithms: DES, 3DES, MD4, MD5, and RC4
  - · Hardware accelerated when possible

## 31.3 Usage and Programming Interface

Many security systems fail due to mistakes in the implementation. Therefore implementations should be left to experts in cryptographic algorithms.

To solve this, the module is supported by an hardened cryptography software library and API delivered through Silicon Labs' Simplicity Studio. The software API is a frontend for performing all supported cryptographic operations both for radio-protocols and applications, and must be used to receive prompt support.

## 31.4 Functional Description

A block diagram of the CRYPTO module is shown in Figure 31.1 CRYPTO Overview on page 1048.

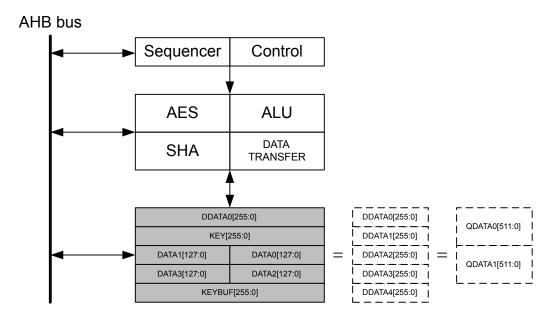

Figure 31.1. CRYPTO Overview

## 31.4.1 Data and Key Registers

The CRYPTO module contains five 256-bit registers. Accelerators are implemented through instructions operating on these registers, either by copying data between registers and external components like the BUFC or through DMA, or by executing instructions on the registers.

Depending on the instruction, the registers can be accessed as 128-bit, 256-bit or 512-bit registers. The registers can also be accessed through different interface registers to achieve different results.

When writing to and reading from the CRYPTO_DATAX, CRYPTO_KEY, CRYPTO_KEYBUF, CRYPTO_DDATAX and CRYPTO_QDATAX registers, the least significant part is accessed first and the most significant part last, see Figure 31.2 CRYPTO Data and Key Register Operation on page 1050. The same is the case for the XOR and byte-access registers for DATA0 and DATA1. It is important to note that some of the 256-bit registers are composed of the 128-bit registers, and both the 512-bit registers are composed of the 256-bit registers.

**Note:** From here on, the 128, 256 and 512-bit registers are named DATAx, DDATAx, QDATAx, etc, And the access-points to these registers are named CRYPTO DATAx, CRYPTO DDATAx, CRYPTO QDATAx, etc.

DATA0 can be accessed through CRYPTO_DATA0 (32-bit), CRYPTO_DATA0XOR (32-bit), CRYPTO_DATA0BYTE (8-bit) and CRYPTO_DATA0XORBYTE (8-bit). Direct access to bytes 12 - 15 is available through CRYPTO_DATA0BYTE12-15 (8-bit). The DATA0XOR (in CRYPTO_DATA0XOR) is used for XOR'ing a value with the current value in DATA0. This is used in a large variety of block cipher modes. All of these registers operate on DATA0.

DATA1 can be accessed through CRYPTO_DATA1 (32-bit) and CRYPTO_DATA1BYTE (8-bit).

The remaining data registers have regular 32-bit access through their respective registers. Note that all data registers require a full read or write to be fully accessed. This means that the 128-bit registers need four 32-bit reads/writes, the 256-bit registers need 8 reads/writes and the 512-bit registers need 16 reads/writes. For a read, if all read accesses are not done, the register will end up as a shifted version of the original value.

**Note:** For byte-wise data accesses (DDATAxBYTE, DATAxBYTE, etc.), all reads and writes must be performed in groups of 4, due to internal buffering and shifting of 32 bits at a time. Accessing a number of bytes that is not a multiple of four can cause data incoherency in all of the data registers.

The KEY and KEYBUF registers are 256 bit wide when AES256 is set in CRYPTO_CTRL. Else they are 128 bit wide. When used as a part of DDATAx and QDATAx, they are always 256 bit wide.

The registers DDATA0BIG and QDATA1BIG produce byte-swapped versions of DDATA0 and QDATA1 respectively. These may be used when a computation requires byte-swapping. An example of this is SHA computation, where data needs to be changed to big endian before CRYPTO can work with it. Little endian data is then loaded in through QDATA1BIG and the resulting little endian hash can be read out from DDATA0BIG, see 31.4.5 SHA.

Except for KEYBUF, the contents of all data registers are lost when going to EM2.

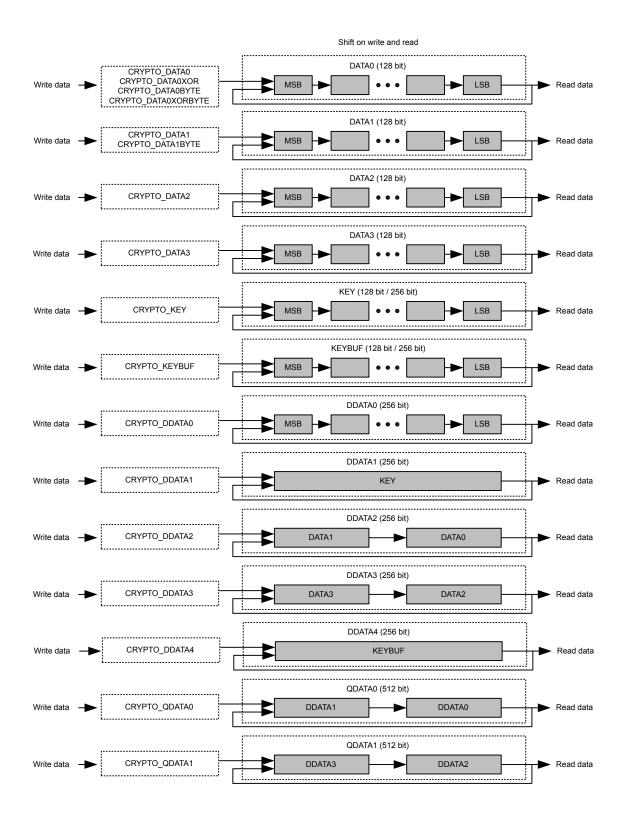

Figure 31.2. CRYPTO Data and Key Register Operation

## 31.4.1.1 DATA0 Zero

DATA0ZERO in CRYPTO_DSTATUS contains status flags indicating if any 32-bit blocks within DATA0 is 0. For example, if DATA0[95:64] is equal to 0x00000000, ZERO64TO95 is set.

### 31.4.1.2 DDATA0 and DDATA1 Quick Observation

DDATA0LSBS in CRYPTO_DSTATUS shows the 4 least significant bits in DDATA0. DDATA0MSBS in CRYPTO_DSTATUS shows the 4 most significant bits of DDATA0, while DDATA1MSB in CRYPTO_DSTATUS shows the msb of DDATA1. These observation bitfields are useful for determining the sign of the value in the data registers without having to read out the full register data register values

The 4 bits observed by DDATA0MSBS will change depending on RESULTWIDTH in CRYPTO_WAC. When using 260-bit results, DDATA0MSBS shows bits 259-256, when using 256-bit results, it is bits 255-252, and for 128-bit results, bits 127-124 can be observed. When RESULTWIDTH is 260 bits, the 4 most significant bits, e.g. bits 259-256 are also available in CRYPTO_DDATA0BYTE32, where they can also be written. Using this register is the only way of inputting the upper 4 bits of a 260-bit number to CRYPTO.

#### 31.4.1.3 Result Width

RESULTWIDTH in CRYPTO_WAC determines the width of the operation when performing arithmetic/shift instructions with CRYPTO. Using less wide results will reduce the current consumption of the CRYPTO module. The higher-order bits that are beyond the selected result width are ignored in the computation of arithmetic/shift operations, however, these higher-order bits will be undefined in the result of such instructions.

When RESULTWIDTH=260BIT, all DDATA registers effectively become 260 bits wide, so that the upper 4 bits are not lost when transferring data from DDATA0 to the other DDATA registers. Likewise, the arithmetic/shift instructions shall consider the full 260-bit values of DDATA0-DDATA4 when used as operation inputs. Note that DDATA0 is the only 260-bit register of which MSBs can be observed/written. The upper 4 bits are observed through DDATA0MSBS in CRYPTO_DSTATUS or through CRYPTO_DDATA0BYTE32. For all DDATAx registers, the extra MSBs are cleared when DDATAx is written. Furthermore, for a particular x, a write to DDATAx or any of its aliased registers will cause DDATAx MSBs to be cleared. Note, writing to KEY/KEYBUF will only clear MSBs of DDATA1/DDATA4 when AES256 mode is set. Likewise, writing to DATA0/DATA2 will not clear DDATA2/DDATA3 MSBs.

Since the DATA0-DATA3 registers are always 128-bit, all bit positions greater than 128 are interpreted as 0 when RESULTWIDTH is greater than 128 bits. However, the assignment instructions DATAxTODDATAy will not zero-out the upper 128 bits of the DDATAy target. Instead, those upper words become undefined after such operations.

#### 31.4.2 Instructions and Execution

The CRYPTO module implements a set of instructions in order to load and manipulate data effectively. These instructions are grouped into four types:

- ALU instructions arithmetic and logical bitwise operations
- Transfer instructions moving data between registers and external peripherals like DMA and the BUFC
- · Conditional instructions conditionally execute instructions based on context
- · Special instructions various crypto and support instructions

A single instruction can be executed by writing INSTR in CRYPTO_CMD. This will execute the instruction, and the interface of CRYP-TO will be locked until the execution has completed. Multiple commands can safely be issued after each other by the CPU as long as NOBUSYSTALL in CRYPTO_CTRL is not set. If CRYPTO gets a new command or a data access request while busy it will then stall the bus, and execute the new command as soon as it is done with the previous one. Note, there are some exceptions to this rule. For example, see 31.4.8 DMA.

Stalling of the bus can be disabled by setting NOBUSYSTALL in CRYPTO_CTRL, however manipulating (reading or writing) registers while running an instruction will result in undefined behaviour. Additionally, if NOBUSYSTALL=0 and a new command or data access request is made while the CRYPTO is simultaneously performing a data transfer instruction, it is possible for system lockup due to bus stalling loops. The safest approach is to always check if an instruction is running by looking at INSTRRUNNING in CRYPTO_STATUS.

Note that this automatic stalling feature does not apply to automated CRYPTO instruction sequences (described next), since there may be cycle delays between individual instructions for which bus accesses are not prevented. For sequences, always check the SEQRUNNING status bit or the SEQDONE interrupt flag to ensure the sequence is finished before attempting CRYPTO register accesses.

### 31.4.2.1 Sequences

For executing a set of instructions, it is more efficient to load them into the CRYPTO module and run them as a sequence. This is done by writing the instructions into CRYPTO_SEQ0-CRYPTO_SEQ4, and marking the end of the instruction sequence with either an END or an EXEC instruction. The END simply means end-of-instructions, while writing EXEC means end-of-instructions and execute immediately.

The five registers allow up to 20 instructions to be loaded. To start execution, either end the instructions with an EXEC instruction, or set SEQSTART in CRYPTO_CMD. CRYPTO will then execute the instructions, starting in CRYPTO_SEQ0, and ending at the first END instruction. SEQRUNNING in CRYPTO_STATUS is set while the sequence is running, and the interrupt flag SEQDONE in CRYPTO_IF will be set when the sequence has completed.

A sequence can be stopped by issuing the SEQSTOP command in the CRYPTO_CMD register. This command also clears the state of ongoing CRYPTO instructions including DMA and BUFC access. Check SEQRUNNING in CRYPTO_STATUS after issuing the SEQSTOP command flag to make sure any ongoing sequence/transfer has completed before accessing data registers again.

### 31.4.2.2 Available Instructions

The available ALU instructions are listed in Table 31.1 ALU Instructions on page 1053, long instructions are listed in Table 31.2 Long Instructions on page 1054, data transfer instructions are listed in Table 31.3 Transfer Instructions on page 1054, conditional instructions are listed in Table 31.4 Conditional Instructions on page 1055 and special instructions are listed in Table 31.5 Special Instructions on page 1055. The tables explains the side-effects of the instructions and shows which registers are affected. For instructions involving BUFC, the BUFC Buffers are defined by READBUFSEL and WRITEBUFSEL in CRYPTO_CTRL for BUFC reads and writes respectively. V0 and V1 in the instructions descriptions can be any of the DDATAx registers and a selection of the DATAx registers. They can be selected using the SELDDATAxDDATAy, SELDATAxDDATAy, SELDATAxDATAy and SELDATAxDATAy instructions. The first register in the instruction will be selected for V0, and the second for V1. This configuration stays even when the sequence is complete, and can also be set up front. The currently selected V0 and V1 can be read V0 and V1 in CRYPTO_CSTATUS.

Table 31.1. ALU Instructions

Instruction	Description	Constraints/Notes
ADD	DDATA0 = V0 + V1	If V0 != DDATA0, then V1 != DDATA0
ADDO	DDATA0 = V0 + V1	Carry is only set, not cleared. If V0 != DDATA0, then V1 != DDATA0
ADDC	DDATA0 = V0 + V1 + carry	If V0 != DDATA0, then V1 != DDATA0
ADDIC	DDATA0 = V0 + V1 + carry << 128	If V0 != DDATA0, then V1 != DDATA0. If resultwidth is 128b, then carry is undefined
MADD	DDATA0 = (V0 + V1) mod P	If V0 != DDATA0, then V1 != DDATA0
MADD32	DDATA0[i] = V0[i] + V1[i]. Word-wise addition	carry is not modified.  If V0 != DDATA0, then V1 != DDATA0
SUB	DDATA0 = V0 - V1	V1 != DDATA0. If V1 is 128b and resultwidth > 128b, then upper 128b are unknown
SUBC	DDATA0 = V0 - V1 - carry	V1 != DDATA0.  If V1 is 128b and resultwidth > 128b, then upper 128b are unknown
MSUB	DDATA0 = (V0 - V1) mod P	V1 != DDATA0. If V1 is 128b and resultwidth > 128b, then upper 128b are unknown
MUL	DDATA0 = DDATA1 * V1. See 31.4.2.3 MULx Details	V1 != DDATA0,DDATA1
MULC	DDATA0 = DDATA1 * V1 + (DDATA0 << MULWIDTH) See 31.4.2.3 MULx Details	.V1 != DDATA0,DDATA1
MMUL	DDATA0 = (DDATA1 * V1) mod P	V1 != DDATA0,DDATA1
MULO	DDATA0 = DDATA1 * V1. See 31.4.2.3 MULx Details	V1 != DDATA0,DDATA1. Carry is only set, not cleared
SHL	DDATA0 = V0 << 1	If V0 is 128b and resultwidth is 260b, then upper 4b are unknown
SHLC	DDATA0 = V0 << 1   carry	If V0 is 128b and resultwidth is 260b, then upper 4b are unknown
SHLB	DDATA0 = V0 << 1   V0[resultwidth-1]	If V0 is 128b and resultwidth is 260b, then upper 4b are unknown
SHL1	DDATA0 = V0 << 1   1	If V0 is 128b and resultwidth is 260b, then upper 4b are unknown
SHR	DDATA0 = V0 >> 1	
SHRC	DDATA0 = V0 >> 1   carry << resultwidth-1	

Instruction	Description	Constraints/Notes
SHRB	DDATA0 = V0 >> 1   V0[0] << resultwidth-1	
SHR1	DDATA0 = V0 >> 1   1 << resultwidth-1	
SHRA	DDATA0 = V0 >> 1   V0[resultwidth-1] << result-width-1	
CLR	DDATA0 = 0	
XOR	DDATA0 = V0 ^ V1	If V0 != DDATA0, then V1 != DDATA0
INV	DDATA0 = ~V0	
CSET	CARRY = 1	
CCLR	CARRY = 0	
BBSWAP128	DDATA0[127:0] = bbswap(V0[127:0])	See 31.4.2.6 BBSWAP128 Instruction
INC	DDATA0 = DDATA0 + 1	
DEC	DDATA0 = DDATA0 - 1	

Table 31.2. Long Instructions

Instruc- tion	Operation	Constraints/Notes
LADD	{DDATA1,DDATA0} = V0 + V1, if V0 != DDATA0. {DDATA1,DDATA0} = {DDATA1,DDATA0} + V1, if V0 = DDATA0	If V0 != DDATA0, then V1 != DDATA0
LADDO	{DDATA1,DDATA0} = V0 + V1, if V0 != DDATA0. {DDATA1,DDATA0} = {DDATA1,DDATA0} + V1, if V0 = DDATA0	Carry is only set, not cleared. If V0 != DDATA0, then V1 != DDATA0
LADDC	{DDATA1,DDATA0} = V0 + V1 + carry, if V0 != DDATA0. {DDATA1,DDATA0} = {DDATA1,DDATA0} + V1 + carry, if V0 = DDATA0	If V0 != DDATA0, then V1 != DDATA0
LADDIC	{DDATA1,DDATA0} = V0 + V1 + carry << 256, if V0 != DDATA0. {DDATA1,DDATA0} = {DDATA1,DDATA0} + V1 + carry << 256, if V0 = DDA	If V0 != DDATA0, then V1 != DDATA0 TA0
LSUB	{DDATA1,DDATA0} = V0 - V1, if V0 != DDATA0. {DDATA1,DDATA0} = {DDATA1,DDATA0} - V1, if V0 = DDATA0	V1 != DDATA0. If V1 is 128b, then upper 128b are unknown
LSUBC	{DDATA1,DDATA0} = V0 - V1 - carry, if V0 != DDATA0. {DDATA1,DDATA0} = {DDATA1,DDATA0} - V1 - carry, if V0 = DDATA0	V1 != DDATA0. If V1 is 128b, then upper 128b are unknown
LMUL	{DDATA1,DDATA0} = DDATA1 * V1	V1 != DDATA0,DDATA1
LMULO	{DDATA1,DDATA0} = DDATA1 * V1	V1 != DDATA0,DDATA1. Carry is only set, not cleared

SELDATAxDATAy	Use DATAx as V0, DATAy as V1	x = 0,1,2; y = 0,1

**Table 31.4. Conditional Instructions** 

Instruction	Operation	Constraints
EXECIFA	Execute following instructions if in part A of sequence	
EXECIFB	Execute following instructions if in part B of sequence	
EXECIFNLAST	Execute following instructions if not in last iteration of sequence	
EXECIFLAST	Execute following instructions if in last iteration of sequence	
EXECIFCARRY	Execute following instructions if carry bit is set	
EXECIFNCARRY	Execute following instructions if carry bit not is set	
EXECALWAYS	Always execute following instructions	

Table 31.5. Special Instructions

Instruction	Operation
END	Ends execution.
EXEC	When written to CRYPTO_SEQx register, automatically triggers execution of all instruction up to this point.
AESENC	DATA0 = AESENC(DATA0)
AESDEC	DATA0 = AESDEC(DATA0)
SHA	DDATA0 = SHA(Q1)

Instruction	Operation
DATA1INC	DATA1 = inc(DATA1). See 31.4.2.5 DATA1INC and DATA1INCCLR Instructions
DATA1INCCLR	DATA1 = clearinc(DATA1). See 31.4.2.5 DATA1INC and DATA1INCCLR Instructions

#### 31.4.2.3 MULx Details

For the MULx instructions (not MMUL), MULWIDTH in CRYPTO_WAC specifies the width of operands DDATA1 (and sometimes V1). This is useful in order to optimize performance because multiplications take the same number of cycles as the bits in the operands plus a couple of cycles for setup.

As with the other ALU instructions, RESULTWIDTH limits the width of the final result of the MULx and MMUL instructions.

### 31.4.2.4 Long Instruction Details

For the Long instructions listed in Table 31.2 Long Instructions on page 1054, RESULTWIDTH in CRYPTO_WAC is ignored and is treated as if it were set to 512 bits. Likewise, MULWIDTH is also ignored and is treated as if it were set to 256 bits.

#### 31.4.2.5 DATA1INC and DATA1INCCLR Instructions

DATA1INC and DATA1INCCLR operate on the 1, 2, 3 or 4 most significant bytes in DATA1, depending on INCWIDTH in CRYP-TO_CTRL. DATA1INC increments these bytes in big endian, while DATA1INCCLR clears the bytes.

#### 31.4.2.6 BBSWAP128 Instruction

The BBSWAP128 instruction copies the contents of the V0 operand to DDATA0 while swapping the bits of the lower 16 bytes. The operand is not changed. This operation is required for GCM. See 31.4.7 GCM and GMAC

## 31.4.2.7 Carry

The carry output from most instructions can be observed through the CARRY bit in CRYPTO_DSTATUS. Shift-instructions set CARRY to the value that is shifted out of the register, addition and multiplication set it on register overflow, and subtraction sets it on borrow, e.g. underflow.

In addition to generating carry information, some instructions also use the current value of CARRY. ADDC, SUBC, SHLC and SHRC all use carry to generate the result. For all of these instructions, carry allows a program to chain instructions together to operate on bigger numbers than allowed by CRYPTO. For example, by chaining first an ADD, and then an ADDC which uses the carry from the ADD operation, two 512-bit numbers can be added. By chaining more instructions, even larger numbers can be manipulated.

Other uses of CARRY include observation. To check if a register is 0, one can subtract 1 using the DEC instruction, and check if goes negative by checking the CARRY bit. CARRY can be set manually and in CRYPTO programs using the CSET and CCLR instructions, which set and clear the CARRY bit.

The MULC instruction does not use CARRY like the other carry instructions (i.e., instructions ending in 'C' such as 'ADDC'), but rather preserves the old contents of the multiplication register.

### 31.4.3 Repeated Sequence

To maximize efficiency, it is desirable to be able to run a set of instructions over multiple blocks of data autonomously. To repeat a sequence over a larger set of data, set LENGTHA in CRYPTO_SEQCTRL to the number of bytes in the set, and BLOCKSIZE to the size of the blocks in the set. The sequence will then be repeated N times, where N is LENGTHA / BLOCKSIZE if LENGTHA is a multiple of BLOCKSIZE, or ceiling( LENGTHA / BLOCKSIZE ) if not. In the latter case, data written by DMA or received from BUFC will be zero-padded up to BLOCKSIZE if it is written to a register which has a size equal to BLOCKSIZE. One notable exception is when LENGTHA is 0. In this case the sequence will still execute once, but the block transfer instructions will not execute.

**Note:** If DMAxRSEL in CRYPTO_CTRL selects a register that is smaller than the specified blocksize, DATATODMAx/DMAxTODATA instructions will not use the full blocksize, but will only transfer enough data to empty/fill the register once. For example, if BLOCKSIZE is set to 64B and DMA0RSEL=DDATA0, the instruction DATATODMA0 will only read 32B instead of 64B. The processing of LENGTHA/B will continue as if all 64B had been transferred.

A repeated sequence can also be made do slightly different operations on different parts of the data set. A sequence can be divided into two parts; part A, and part B. By configuring LENGTHA in CRYPTO_SEQCTRL to the length of part A, and LENGTHB in CRYPTO_SEQCTRLB to the length of part B, CRYPTO will first run iterations over part A, knowing it is A, and then part B, knowing it is part B. By using the conditional instructions listed in Table 31.4 Conditional Instructions on page 1055, a program can execute different instructions depending on whether it is in part A or part B.

### 31.4.4 AES

The AES core operates on data in the 128-bit register DATA0 using the either a 128-bit or 256-bit key from the KEY register. The key width is specified by AES256 in CRYPTO_CTRL. AES operations are implemented as the AESENC and AESDEC instructions, for AES encryption and AES decryption respectively. An overview of the AES functionality is shown in Figure 31.3 CRYPTO AES Overview on page 1058.

AES encryption and decryption enables various block cipher modes like ECB, CTR, CBC, PCBC, CFB, OFB, CBC-MAC, GMAC, CCM, CCM*, and GCM.

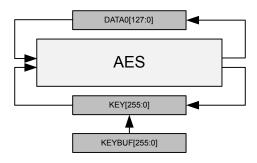

Figure 31.3. CRYPTO AES Overview

The input data before encryption is called the PlainText and output from the encryption is called CipherText. For encryption, the key is called PlainKey. After encryption, the resulting key in the KEY registers is the CipherKey. This key must be loaded into the KEY registers prior to the decryption. After one decryption, the resulting key will be the PlainKey. The resulting PlainKey/CipherKey is only dependent on the value in the KEY registers before encryption/decryption. The resulting keys and data are shown in Figure 31.4 CRYPTO Key and Data Definitions on page 1058.

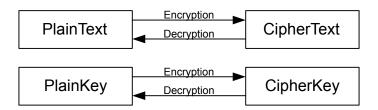

Figure 31.4. CRYPTO Key and Data Definitions

The KEY is by default loaded from KEYBUF prior to each AESENC or AESDEC instruction. If the KEY is not to be overwritten, key buffering should be disabled (KEYBUFDIS in CRYPTO_CTRL). Disabling key buffering also allows the use of key loading through DMA.

The data and key orientation in the CRYPTO registers are shown in Figure 31.5 CRYPTO Data and Key Orientation as Defined in the Advanced Encryption Standard on page 1059.

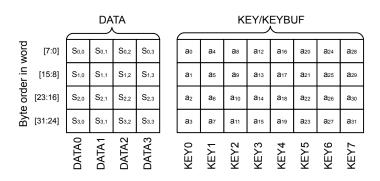

Figure 31.5. CRYPTO Data and Key Orientation as Defined in the Advanced Encryption Standard

### 31.4.5 SHA

The CRYPTO SHA instruction implements SHA-1 with a 160-bit digest or SHA-2 with a 224-bit digest (SHA-224) or 256-bit digest (SHA-256). Depending on SHAMODE in CRYPTO_CTRL, SHA-1, SHA-224 or SHA-256 will be run on the data in QDATA1, and the result will be put on DDATA0. The contents in QDATA1 will be destroyed in the process.

To run SHA on a dataset, it must first be pre-processed by appending a bit '1' to the message, then padding the data with '0' bits until the message length in bits modulo 512 is 448. Then append the length of the message before pre-processing as a 64-bit big-endian integer. This pre-processing is known as MD-strengthening, and must be done by software before processing with the CRYPTO module.

The pre-processed data can now be run through the CRYPTO module. Begin by writing the values listed in Table 31.6 SHA Init Values on page 1060 to CRYPTO_DDATA1 from top to bottom, then execute the instructions listed in Table 31.7 SHA Preparations on page 1060.

Table 31.6. SHA Init Values

SHA-1	SHA-224	SHA-256
0x67452301	0xC1059ED8	0x6A09E667
0xEFCDAB89	0x367CD507	0xBB67AE85
0x98BADCFE	0x3070DD17	0x3C6EF372
0x10325476	0xF70E5939	0xA54FF53A

0x0000000	0x68581511	0x9B05688C
0x0000000	0x64F98FA7	0x1F83D9AB
0x0000000	0xBEFA4FA4	0x5BE0CD19

**Table 31.7. SHA Preparations** 

STEP	ACTION	Description
STEP0	DDATA1TODDATA0	Copy init data to DDATA0
STEP1	SELDDATA0DDATA1	Select DDATA0 and DDATA1 as operands for SHA instruction

Then, for each 512-bit block, write the block to CRYPTO_QDATA1BIG, execute the instructions listed in Table 31.8 SHA for 512-bit Block on page 1060.

Table 31.8. SHA for 512-bit Block

STEP	ACTION	Description
STEP0	SHA	Perform SHA operation on data in QDATA1
STEP1	MADD32	Accumulate with previous data in DDATA1
STEP2	DDATA0TODDATA1	Copy hash to DDATA1

After the last iteration, the resulting hash can be read out from CRYPTO_DDATA0BIG.

#### 31.4.6 ECC

The CRYPTO module implements support for Elliptic Curve Cryptography through the modular instructions MADD, MMUL and MSUB, which perform modular addition, multiplication and subtraction respectively. The instructions can operate on a set of both prime fields GF(p) and binary fields  $GF(2^m)$ .

The type of modular arithmetic used and the modulus for the modular operations are specified by MODOP and MODULUS in CRYP-TO WAC respectively. Changing these in the middle of an operation leads to undefined behaviour.

#### 31.4.7 GCM and GMAC

CRYPTO implements support for Galois/Counter Mode (GCM), and also Galois Message Authentication Code (GMAC), by providing AES instructions and allowing multiplication on the field  $GF(2^{128})$  defined by the polynomial  $x^{128} + x^{7} + x^{2} + x + 1$ .

Note: BBSWAP128 needs to be applied to both operands and the result of the MMUL instruction when using it for GCM and GMAC

Efficient sequencer programs can be set up to perform GCM authentication and encryption/decryption on data from either BUFC, DMA, or CPU. To achieve a single-pass solution, LENGTHA in CRYPTO_SEQCTRL is set to the length of the authentication part, and LENGTHB is set to the length of the rest of the message. Conditional instructions can then be used to make sure the two parts of the message are processed correctly. A similar approach is used to implement CCM.

### 31.4.8 DMA

The CRYPTO module has 5 DMA request signals (see Table 31.9 DMA Signals on page 1061) split over 2 internal DMA channels: DMA0 and DMA1. These DMA channels are not associated with channel 0 and 1 of the system DMA, and any system DMA channel can serve any of the 5 DMA requests. See the DMA chapter for information on how to configure the system DMA.

The DMA signals are set through the use of DMA oriented instructions, and cleared by reading or writing the respective CRYPTO data registers.

Name	Set on	Cleared on				
DMA0WR	Instruction DMA0TODATA, and DMA0TODATAXOR if COMBDMA0WEREQ in CRYPTO_CTRL is set	Full CRYPTO_DATA0, CRYPTO_DDATA0, CRYPTO_DDATA0BIG or CRYPTO_QDATA0 write, or CRYPTO_DDATA0XOR if COMBDMA0WEDMAREQ in CRYPTO_CTRL is set				
DMA0XORWR	Instruction DMA0TODATAXOR	Full CRYPTO_DATA0XOR write				
DMA0RD	Instructions DATATODMA0	Full CRYPTO_DATA0, CRYPTO_DDATA0, CRYP-TO_DDATA0BIG or CRYPTO_QDATA0 read, depending on DMA0MODE in CRYPTO_CTRL				
DMA1WR	Instructions DMA1TODATA	Full CRYPTO_DATA1, CRYPTO_DDATA1, CRYPTO_QDATA1 or CRYPTO_QDATA1BIG write				
DMA1RD	Instructions DATATODMA1	Full CRYPTO_DATA1, CRYPTO_DDATA1, CRYP- TO_QDATA1 or CRYPTO_QDATA1BIG read, depend- ing on DMA1MODE in CRYPTO_CTRL				

Table 31.9. DMA Signals

**Note:** DMAxRSEL in CRYPTO_CTRL has to be set to the data registers that are to be read using the respective DMA channels on a DATATODMAx instruction. As an important note, DMAxRSEL in CRYPTO_CTRL selects what is read from **any** of the selectable read registers during an ongoing DATATODMAx transfer .

When a DMA oriented CRYPTO instruction is used (either through a STEP in a Sequence or through CRYPTO_CMD), the corresponding DMA signal is set. The instruction is complete when the entire source/destination is read/written (e.g. if DMA0TODATA is used, the operation is complete when a total of 128 valid bits have been written through the CRYPTO_DATA0 register). DMAACTIVE in CRYPTO_STATUS is set while CRYPTO is working on a DMA-related instruction, e.g. waiting for the DMA to read or write data to CRYPTO (see 31.4.8.1 DMA Initial Bytes Skip).

Normally, when a sequence or instruction is executed, access to most CRYPTO registers will stall the CPU or DMA that is trying to access CRYPTO until the operation is done, preventing accesses to CRYPTO that could potentially interfere with an operation. During DMA operations, all non-DMA registers are writeable and readable, but progress through the DMA operation will only be tracked with the registers targeted by the DMA operation (i.e., if the DMA operation is supposed to transfer 3 words to DATA0, the DMA can first choose to transfer data to e.g. DATA3, and then fulfill the transfer to DATA0).

Because the bus interface to CRYPTO is normally locked outside of DMA transfers, a wrongly set up DMA transfer (e.g., transferring one byte too many) may lock up the interface. One way to assist in debugging such issues can be setting NOBUSYSTALL in CRYPTO_CTRL. This will prevent any stall on CRYPTO register accesses during sequences and instructions. Use this option with care, as modifying a register that is being used by CRYPTO can lead to undefined behavior.

### 31.4.8.1 DMA Initial Bytes Skip

The DMA must be configured to use 32-bit transfer size. This normally would imply that the source data must be aligned to a 4 byte address boundary. However, it is possible to skip the initial bytes (1 to 3) when using DMA to write to DATA0 or DATA1 through a CRYPTO instruction operation. The number of bytes to skip are set in DMA0SKIP and DMA1SKIP in CRYPTO_SEQCTRL. This implies that if DMA0SKIP is set to another value than 0, the initial DMA access will require 5 DMA transfers, even though only 4x32-bit is required.

**Note:** Any valid unused bytes from a previous DMA write will be used before new DMA data is requested. This data is invalidated by using STOP in CRYPTO_CMD.

#### 31.4.8.2 DMA Unaligned Read/Write

Except for DATA0 and DATA1, which can be loaded bytewise using the CRYPTO_DATA0BYTE, CRYPTO_DATA0XORBYTE and CRYPTO_DATA1BYTE registers, the CRYPTO data registers are loaded 32-bits at a time. Special care must be taken when using the DMA and the data buffer is not aligned to a 32-bit address, because the DMA does not directly support 32-bit unaligned accesses.

As an example, let an in-memory 16-byte data buffer start at address 4*N + M and end at the byte before. 4*N + 16 + M, where M is between 0 and 3 inclusive. With an M=0, we have fully aligned accesses, and everything is fine. For M>0 however, the access is unaligned. If M=1, that means that the first 32-bit aligned word of the memory buffer contains 1 byte before the buffer, and 3 bytes of the buffer. Similarly, the last 32-bit aligned word of the memory buffer contains the last byte of the buffer, and three bytes after the buffer.

When doing an unaligned read, we want to only pass the 16 bytes of the buffer to the CRYPTO module. Not the N bytes before in the 32-bit aligned word, and not the 4-N words at the end. To achieve this, set DxDMAREADMODE in CRYPTO_CTRL to either UN-ALIGNEDFULL or UNALIGNEDLENLIMIT, and set DATAxDMASKIP in CRYPTO_SEQCTRL equal to N. When reading in data using a DMA-oriented instruction to DATAx, DDATAx or QDATAx, the read will now only contain the 16 bytes, and not the N bytes before or 4-N words after. Note that in this case, the DMA has to be set up to transfer 5 32-bit words instead of the effective 4.

Being able to read unaligned data does not solve all cases however. If data is to be written back to the buffer after passing through CRYPTO, e.g. when doing an in-place encryption or decryption, it is very undesirable to actually modify the N bytes before and 4-N bytes after the buffer. This is solved using the UAR-suffixed registers in CRYPTO when reading data out from the CRYPTO module, e.g. CRYPTO_DATA0UAR, CRYPTO_DATA1UAR, CRYPTO_DDATA0UAR, CRYPTO_DDATA1UAR, CRYPTO_DDATA1UAR, CRYPTO_DDATA1UAR, CRYPTO_DDATA0UAR, etc. When an unaligned buffer is written to a CRYPTO buffer, CRYPTO stores the N first bytes and the 4-N last bytes internally. When reading out from an UAR register, these bytes are placed back into the data if DATAxDMAPRES is set in CRYPTO_SEQCTRL.

Note that the latter case only works if the first N and the last 4-N bytes are not changed while CRYPTO works on the data. Internally CRYPTO has 2 buffers for the bytes before and after. The first one is connected to read/write of the DATA0, DDATA0 and QDATA0 registers, and the second is connected to the DATA1, DDATA1 and QDATA1 registers.

If DMAxRMODE in CRYPTO_CTRL is set to FULL or UNALIGNEDFULL and the corresponding DMAxPRES in CRYPTO_SEQCTRL is set, then a whole number of data buffers have to be written by the DMA. In all other cases, it is enough to write the number of 32-bit words to pass all LENGTH bits to the target CRYPTO buffer.

#### 31.4.9 BUFC Data Transfer

To allow automatic encryption/decryption or other operations on radio data, CRYPTO has instructions for moving data from and to BUFC, the Buffer Controller. Both DATA0 and DATA1 can be loaded with data from the buffer selected by READBUFSEL (CRYPTO_CTRL register) as shown in Figure 31.6 CRYPTO BUFC Data Transfer on page 1063. Similarly, the content of DATA0 and DATA1 can be written to the buffer selected by WRITEBUFSEL (also in the CRYPTO_CTRL register).

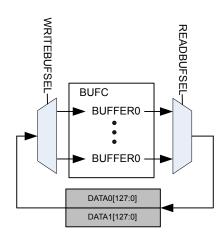

Figure 31.6. CRYPTO BUFC Data Transfer

When reading from CRYPTO to the BUFC, the number of bytes read are determined by the DMAxRMODE configuration in CRYPTO_CTRL. If it is set to either LENLIMIT or LENLIMITBYTE, only the number of bytes given by LENGTH in CRYPTO_SEQCTRL are transferred. Else the full width of the last buffer is also written, e.g. a full number of 16-byte buffers are written to the BUFC.

### Note:

The buffer selected by READBUFSEL and WRITEBUFSEL in the CRYPTO_CTRL registers must be appropriately configured in the BUFC module prior to using instructions involving BUFC.

All BUFC reads start at the current BUFC read pointer, and move the pointer according to the number of bytes read. BUFC writes normally also work in the same way, starting at the current BUFC write pointer, and moving it the right number of positions. For BUFC XOR writes, software has the option to change this by setting either of DATAxTOBUFXOROW in CRYPTO_CTRL. With this bit set, the BUFC write pointer will be reset to the start of the previous write before writing to the BUFC. Using this feature, BUFC data can be written with using the DATAxTOBUFC instructions, and then XOR'ed with another set of data using the DATAxTOBUFCXOR instruction.

BUFACTIVE in CRYPTO STATUS is set while CRYPTO is reading or writing from/to the BUFC.

## 31.4.10 Debugging

There are multiple ways of debugging CRYPTO sequences. The most straight-forward way is to write individual instructions to INSTR in CRYPTO CMD. An instruction can be written, and data can be read out and examined before running another instruction.

Running individual instructions to debug a program falls short when working with repeated sequences. In these cases, a sequence is run multiple times over a set of data. This cannot be directly replicated with individual instructions

To debug a sequence, set HALT in CRYPTO_SEQCTRL. When set, CRYPTO requires software or the debugger to step it through each instruction in the sequence. To step through the sequence, set SEQSTEP in CRYPTO_CMD. This will execute the current instruction, and make CRYPTO ready to execute the next one.

When stepping through a sequence, the current instruction index can be read from SEQIP in CRYPTO_CSTATUS. SEQSKIP, also in CRYPTO_CSTATUS tells whether the next instruction will be executed or not, based on previous conditionals in the program. SEQ-PART in CRYPTO_CSTATUS shows whether CRYPTO is currently in part A or B of a sequence. Even with NOBUSYSTALL in CRYPTO_CTRL cleared, read and write accesses to CRYPTO will be allowed when CRYPTO is waiting to be stepped. This is to allow data registers to be inspected during debugging.

**Note:** The data registers in CRYPTO (those marked read-actionable) require shifting of data in order to return the result. For this reason, reading these registers will have no effect and will return unknown values during normal debugger read accesses (see 6.3.7 Debugger Reads of Actionable Registers).

## 31.4.11 Example: Cipher Block Chaining (CBC)

In the following the setup and operation of CBC is explained and illustrated. The example can easily be adjusted to perform other cipher block modes.

## 31.4.11.1 CBC Encryption

In CBC encryption, the cipher input is the PlainText XOR'ed with the previous cipher output (an initialization vector IV is used during the first block). This mode is easily implemented using the CRYPTO instruction sequence BUFTODATA0XOR, AESENC then DATA0TOBUF. The BUFTODATA0XOR reads data from the buffer set by READBUFSEL and XOR's it with the content in DATA0. Then the cipher operation is performed and subsequently the DATA0TOBUF writes the content of DATA0 to the buffer set by WRITEBUFSEL (normally the same as READBUFSEL).

Prior to the operation, the initialization vector IV and key must be loaded to DATA0 and KEYBUF, respectively. Additionally, the total number of bytes to be included in the repeated sequence must be set in LENGTHA in CRYPTO_SEQCTRL. Finally, the buffers selected by READBUFSEL and WRITEBUFSEL must be configured correctly in the BUFC. The sequence is started by issuing the SEQ-START command in CRYPTO_CMD.

In Figure 31.7 CBC Encryption Operation on page 1065 the CBC encryption is illustrated and in Table 31.10 CBC Encryption Steps on page 1065 each step in the loop is explained.

**CBC Encryption** 

#### Loop 0 Loop 1 Init P₀ P1 DATA0 IV $C_0$ $C_1$ XOR XOR IV $C_0$ DATA1 **BUF** P₁ $C_0$ $C_1$ $P_0$ 1 2 3 2 3 1

Figure 31.7. CBC Encryption Operation

Steps

Steps

Table 31.10. CBC Encryption Steps

STEP	ACTION	Description
STEP0	BUFTODATA0XOR	Move data (PlainText, P _i ) from buffer to DATA0 using XOR write.
STEP1	CIPHER	The AES Cipher Core operates on DATA0
STEP2	DATA0TOBUF	The cipher output C _i is written to the buffer.

## 31.4.11.2 CBC Decryption

In CBC decryption, CipherText ( $C_i$ ) is used as input to the Cipher Core. The output from the Cipher Core is XOR'ed with the CipherText from the previous block  $C_{i-1}$  to form the PlainText  $P_i$  (an initialization vector IV is used as  $C_{i-1}$  during the first block).

Because each block requires both  $C_{i-1}$  and  $C_i$ , decryption is somewhat more complex than encryption. Nevertheless, CBC decryption can be performed in as a repeated sequence by having  $C_{i-1}$  from the previous block stored in DATA1 and then writing it to buffer without updating the write pointer (using the DATA1TOBUF instruction). Then the cipher output is XOR'ed with  $C_{i-1}$  in the buffer by using the DATA0TOBUFXOR instruction.

In Figure 31.8 CBC Decryption Operation on page 1066 the CBC decryption is illustrated and in Table 31.11 CBC Decryption Steps on page 1066 each step in the loop is explained.

# **CBC** Decryption

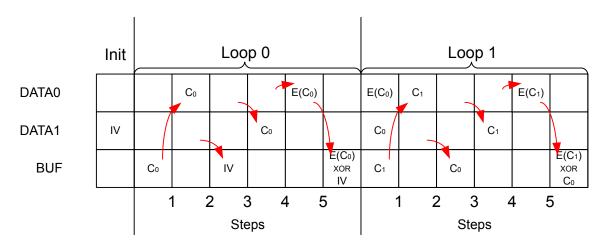

Figure 31.8. CBC Decryption Operation

Table 31.11. CBC Decryption Steps

STEP	ACTION	Description
STEP0	BUFTODATA0	Moves data (CipherText, C _i ) from buffer to DATA0
STEP1	DATA1TOBUF	DATA1 (CipherText, C _{i-1} ) is moved to buffer. BUFC Write pointer is not incremented!
STEP2	DATA0TODATA1	Value of DATA0 is copied to DATA1.
STEP3	CIPHER Operation	The AES Cipher Core operates on DATA0
STEP4	DATA0TOBUFXOR	The cipher output is XOR'ed with $C_{i-1}$ (placed in the buffer at Step 2) to form the PlainText, $P_i$ .

## 32. GPIO - General Purpose Input/Output

#### **Quick Facts**

#### What?

The General Purpose Input/Output (GPIO) is used for pin configuration, direct pin manipulation and sensing, as well as routing for peripheral pin connections.

#### Why?

Easy to use and highly configurable input/output pins are important to fit many communication protocols as well as minimizing software control overhead. Flexible routing of peripheral functions helps to ease PCB layout.

#### How?

Each pin on the device can be individually configured as either an input or an output with several different drive modes. Also, individual bit manipulation registers minimizes control overhead. Peripheral connections to pins can be routed to several different locations, thus solving congestion issues that may arise with multiple functions on the same pin. Fully asynchronous interrupts can also be generated from any pin.

### 32.1 Introduction

In the EFR32xG12 Wireless Gecko devices the General Purpose Input/Output (GPIO) pins are organized into ports with up to 16 pins each. These GPIO pins can individually be configured as either an output or input. More advanced configurations like open-drain, open-source, and glitch filtering can be configured for each individual GPIO pin. The GPIO pins can also be overridden by peripheral pin connections, like Timer PWM outputs or USART communication, which can be routed to several locations on the device. The GPIO supports up to 16 asynchronous external pin interrupts, which enable interrupts from any pin on the device. Also, the input value of a pin can be routed through the Peripheral Reflex System to other peripherals.

Note: To use the GPIO, the GPIO clock must first be enabled in CMU_HFBUSCLKEN0. Setting this bit enables the HFBUSCLK for the GPIO.

#### 32.2 Features

- · Individual configuration for each pin
  - · Tristate (reset state)
  - Push-pull
  - · Open-drain
  - · Pull-up resistor
  - · Pull-down resistor
  - · Drive strength
    - 1 mA
    - 10 mA
  - Slewrate
  - · Over Voltage Tolerance
- EM4 IO pin retention
  - · Output enable
  - · Output value
  - · Pull enable
  - · Pull direction
  - · Over Voltage Tolerance
- · EM4 wake-up on selected GPIO pins
- · Glitch suppression input filter
- · Alternate functions (e.g. peripheral outputs and inputs)
  - · Routed to several locations on the device
  - · Pin connections can be enabled individually
  - · Output data can be overridden by peripheral
  - · Output enable can be overridden by peripheral
- · Toggle register for output data
- · Dedicated data input register (read-only)
- · Interrupts
  - · 2 Interrupt lines using either levels or edges
    - · EM4 wake-up pins are selectable for level interrupts
    - · All GPIO pins are selectable for edge interrupts
  - · Separate enable, status, set and clear registers
  - · Asynchronous sensing
  - · Rising, falling or both edges
  - · High or low level detection
  - · Wake up from EM0 Active-EM3 Stop
- · Peripheral Reflex System producer
  - · All GPIO pins are selectable
- · Configuration lock functionality to avoid accidental changes

### 32.3 Functional Description

An overview of the GPIO module is shown in Figure 32.1 Pin Configuration on page 1108. The GPIO pins are grouped into 16-pin ports. Each individual GPIO pin is called Pxn where x indicates the port (A, B, C ...) and n indicates the pin number (0,1,....,15). Fewer than 16 bits may be available on some ports, depending on the total number of I/O pins on the package. After a reset, both input and output are disabled for all pins on the device, except for the Serial Wire Debug pins.

To use a pin, the Mode Register (GPIO_Px_MODEL/GPIO_Px_MODEH) must be configured for the pin to make it an input or output. These registers can also do more advanced configuration, which is covered in 32.3.1 Pin Configuration. When the port is configured as an input or an output, the Data In Register (GPIO_Px_DIN) can be used to read the level of each pin in the port (bit n in the register is connected to pin n on the port). When configured as an output, the value of the Data Out Register (GPIO_Px_DOUT) will be driven to the pin.

The DOUT value can be changed in 4 different ways:

- · Writing to the GPIO_Px_DOUT register
- · Writing the BITSET address of the GPIO_Px_DOUT register sets the DOUT bits
- · Writing the BITCLEAR address of the GPIO_Px_DOUT register clears the DOUT bits
- Writing the GPIO_Px_DOUTTGL register toggles the corresponding DOUT bits

Reading the GPIO_Px_DOUT register will return its contents. Reading the GPIO_Px_DOUTTGL register will return 0.

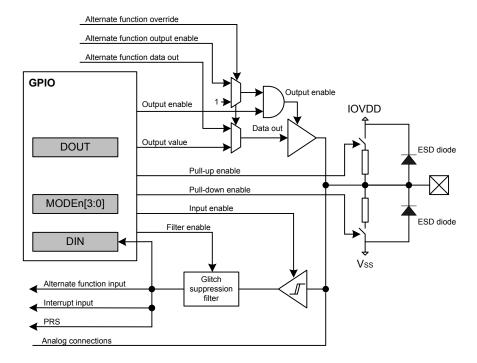

Figure 32.1. Pin Configuration

#### 32.3.1 Pin Configuration

In addition to setting the pins as either outputs or inputs, the GPIO_Px_MODEL and GPIO_Px_MODEH registers can be used for more advanced configurations. GPIO_Px_MODEL contains 8 bit fields named MODEn (n=0,1,..7) which control pins 0-7, while GPIO_Px_MODEH contains 8 bit fields named MODEn (n=8,9,..15) which control pins 8-15. In some modes GPIO_Px_DOUT is also used for extra configurations like pull-up/down and glitch suppression filter enable. Table 32.1 Pin Configuration on page 1109 shows the available configurations.

**Table 32.1. Pin Configuration** 

MODEn	Input	Output	DOUT	Pull- down	Pull- up	Alt Port Ctrl	Input Filter	Description
DISABLED	Disabled	Disabled	0					Input disabled
			1		On			Input disabled with pull-up
INPUT	Enabled		0					Input enabled
	if not DINDIS		1				On	Input enabled with filter
INPUTPULL			0	On				Input enabled with pull-down
			1		On			Input enabled with pull-up
INPUTPULLFILTER			0	On			On	Input enabled with pull- down and filter
			1		On		On	Input enabled with pull-up and filter
PUSHPULL		Push-	х					Push-pull
PUSHPULLALT		pull	х			On		Push-pull with alternate port control values
WIREDOR		Open	х					Open-source
WIREDORPULLDOWN		Source (Wired- OR)	х	On				Open-source with pull-down
WIREDAND		Open	х					Open-drain
WIREDANDFILTER		Drain (Wired-	х				On	Open-drain with filter
WIREDANDPULLUP		AND)	х		On			Open-drain with pull-up
WIREDANDPULLUPFILTER			х		On		On	Open-drain with pull-up and filter
WIREDANDALT			х			On		Open-drain with alternate port control values
WIREDANDALTFILTER			х			On	On	Open-drain with alternate port control values and filter
WIREDANDALTPULLUP			х		On	On		Open-drain with alternate port control values and pull-up
WIREDANDALTPULLUPFILTER			х		On	On	On	Open-drain with alternate port control values, pull-up and filter

MODEn determines which mode the pin is in at a given time. Setting MODEn to DISABLED disables the pin, reducing power consumption to a minimum. When the output driver, input driver and Over Voltage Tolerance is disabled, the pin can be used as a connection for an analog module. An input is enabled by setting MODEn to any value other than DISABLED while DINDIS for the given port is cleared.

Set DINDIS to disable the input of a gpio port. The pull-down and glitch filter function can optionally be applied to the input, see Figure 32.2 Tristated Output With Optional Pull-up or Pull-down on page 1110.

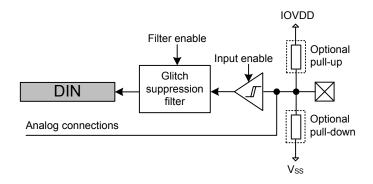

Figure 32.2. Tristated Output With Optional Pull-up or Pull-down

When MODEn is PUSHPULL or PUSHPULLALT, the pin operates in push-pull mode. In this mode, the pin can have alternate port control values and can be driven either high or low, dependent on the value of GPIO_Px_DOUT. The push-pull configuration is shown in Figure 32.3 Push-Pull Configuration on page 1110.

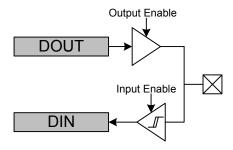

Figure 32.3. Push-Pull Configuration

When MODEn is WIREDOR or WIREDORPULLDOWN, the pin operates in open-source mode (with a pull-down resistor for WIREDORPULLDOWN). When driving a high value in open-source mode, the pull-down is disconnected to save power.

When the mode is prefixed with WIREDAND, the pin operates in open-drain mode as shown in Figure 32.4 Open-drain on page 1110. In open-drain mode, the pin can have an input filter, a pull-up, alternate port control values or any combination of these. When driving a low value in open-drain mode, the pull-up is disconnected to save power.

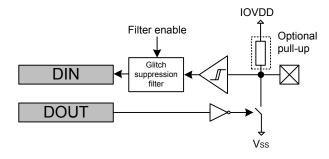

Figure 32.4. Open-drain

### 32.3.1.1 Over Voltage Tolerance

Over voltage capability is available for most pins. If available, it allows the pin to be used at the minimum of IOVDD + 2V and 5.5V (for 5V tolerant pads). The data sheet specifies which pins can be used as 5V tolerant pins. Default over voltage is enabled for each pin supporting that feature. Over voltage tolerance (OVT) can be disabled on a per pin basis. The over voltage tolerance feature applied to the selected pins is configured in the GPIO_Px_OVTDIS register. Disabling the over voltage tolerance for a pin will provide less distortion on that pin, which is useful when the pin is used as analog input.

Note: The VDAC (and OPAMPs) can drive outputs above IOVDD and therefore the involved pads typically require OVT to be be enabled.

#### 32.3.1.2 Alternate Port Control

The Alternate Port Control allows for additional flexibilty of port level settings. A user may setup two different port configurations (normal and alternate modes) and select which is applied on a pin by pin bases. For example you may configure half of port A to use the low drive strength setting (normal mode) while the other half uses high drive strength (alternate mode).

Alternate port control is enabled when MODEn is set to any of the ALT enumerated modes (ie. PUSHPULLALT). When MODEn is an alternate mode, the pin uses the alternate port control values specified in the DINDISALT, SLEWRATEALT, and DRIVESTRENGTHALT fields in GPIO_Px_CTRL. In all other modes, the port control values are used from the DINDIS, SLEWRATE, and DRIVESTRENGTH fields in GPIO_Px_CTRL.

## 32.3.1.3 Drive Strength

The drive strength can be applied to pins on a port-by-port basis. The drive strength applied to pins configured using normal MODEn settings can be controlled using the DRIVESTRENGTH field in GPIO_Px_CTRL. The drive strength applied to pins configured using alternate MODEn settings can be controlled using the DRIVESTRENGTHALT field.

#### 32.3.1.4 Slewrate

The slewrate can be applied to pins on a port-by-port basis. The slewrate applied to pins configured using normal MODEn settings can be controlled using the SLEWRATE fields in GPIO_Px_CTRL. The slewrate applied to pins configured using the alternate MODEn settings can be controlled using the SLEWRATEALT field.

#### 32.3.1.5 Input Disable

The pin inputs can be disabled on a port-by-port basis. The input of pins configured using the normal MODEn settings can be disabled by setting DINDIS in GPIO_Px_CTRL. The input of pins configured using the alternate MODEn settings can be disabled by setting DINDISALT.

### 32.3.1.6 Configuration Lock

GPIO_Px_MODEL, GPIO_Px_MODEH, GPIO_Px_CTRL, GPIO_Px_PINLOCKN, GPIO_Px_OVTDIS, GPIO_EXTIPSELL, GPIO_EXTIPSELH, GPIO_EXTIPINSELL, GPIO_EXTIPINSELH, GPIO_INSENSE, GPIO_ROUTEPEN, and GPIO_ROUTELOC0 can be locked by writing any value other than 0xA534 to GPIO_LOCK. Writing the value 0xA534 to the GPIOx_LOCK register unlocks the configuration registers.

In addition to configuration lock, GPIO_Px_MODEL, GPIO_Px_MODEH, GPIO_Px_DOUT, GPIO_Px_DOUTTGL, and GPIO_Px_OVT-DIS can be locked individually for each pin by clearing the corresponding bit in GPIO_Px_PINLOCKN. When a bit in the GPIO_Px_PINLOCKN register is cleared, it will stay cleared until reset.

### 32.3.2 EM4 Wake-up

It is possible to trigger a wake-up from EM4 using any of the selectable EM4WU GPIO pins. The wake-up request can be triggered through the pins by enabling the corresponding bit in the GPIO_EM4WUEN register. When EM4 wake-up is enabled for the pin, the input filter is enabled during EM4. This is done to avoid false wake-up caused by glitches. In addition, the polarity of the EM4 wake-up request can be selected using the GPIO_EXTILEVEL register.

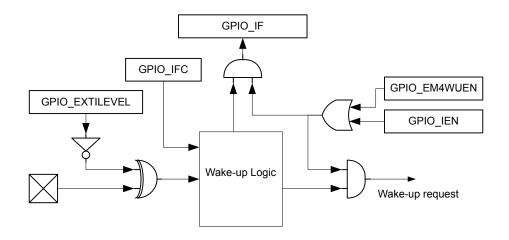

Figure 32.5. EM4 Wake-up Logic

The pins used for EM4 wake-up must be configured as inputs with glitch filters using the GPIO_Px_MODEL/GPIO_Px_MODEH register. If the input is disabled and the wakeup polarity is low, a false wakeup will occur when entering EM4. If the input is enabled, the glitch filtered is disabled, and the polarity is set low, a glitch will occur when going into EM4 that will cause an immediate wake-up. Before going down to EM4, it is important to clear the wake-up logic by setting the GPIO_IFC bit, which clears the wake-up logic, including the GPIO_IF register. It is possible to determine which pin caused the EM4WU by reading the GPIO_IF register. The mapping between EM4WU pins and the bit indexes in the GPIO_EM4WUEN, GPIO_EXTILEVEL, GPIO_IFC, GPIO_IFS, GPIO_IEN, and GPIO_IF registers is as follows:

Table 32.2. EM4WU Register Bit Index to EM4WU Pin Mapping

EM4WU Register Bit Indexes	EM4WU Pin	
16	GPIO_EM4WU0	
17	GPIO_EM4WU1	
18	GPIO_EM4WU2	
19	GPIO_EM4WU3	
31	GPIO_EM4WU15	

### 32.3.3 EM4 Retention

By default, GPIO pins revert back to their reset state when EM4 is entered. The GPIO pins can be configured to retain the settings for output enable, output value, pull enable, pull direction and over voltage tolerance while in EM4.

EM4 GPIO retention is controlled with the EM4IORETMODE field in the EMU_EM4CTRL register. Setting EM4IORETMODE to EM4EXIT will cause retention to persist while in EM4 and reset the GPIOs during wakeup. Setting EM4IORETMODE to SWUNLATCH will cause the retention to persist until the EM4UNLATCH bit is written by software. Note that when using SWUNLATCH, the GPIO register values are still reset on wakeup from EM4. In order to ensure that the GPIO state does not change, sofware must re-write the GPIO registers before setting EM4UNLATCH and ending EM4 GPIO retention. See the EMU chapter for additional documentation on its registers and the EM4UNLATCH bit.

#### 32.3.4 Alternate Functions

Alternate functions are connections to pins from peripherals, i.e. Timers, USARTs, etc.. These peripherals contain route registers, where the pin connections are enabled. In addition, the route registers contain a location bit field that configures which pin an output of that peripheral will be connected to if enabled. After connecting a peripheral, the pin configuration stays as set in GPIO_Px_MODEL, GPIO_Px_MODEH and GPIO_Px_DOUT registers. For example, the pin configuration must be set to output enable in GPIO_Px_MODEL or GPIO_Px_MODEH for a peripheral to be able to use the pin as an output.

It is not recommended to select two or more peripherals as output on the same pin. The reader is referred to the pin map section of the device data sheet for more information on the possible locations of each alternate function.

#### 32.3.4.1 Analog Connections

When using the GPIO pin for analog functionality, it is recommended to disable the over voltage tolerance by setting the corresponding pin in the GPIO_Px_OVTDIS register and setting the MODEn in GPIO_Px_MODEL or GPIO_Px_MODEH equal to DISABLE to disable the input sense, output driver and pull resistors.

### 32.3.4.2 Debug Connections

### 32.3.4.2.1 Serial Wire Debug Connection

The SW Debug Port is routed as an alternate function and the SWDIO and SWCLK pin connections are enabled by default with internal pull up and pull down resistors, respectively. It is possible to disable these pin connections (and disable the pull resistors) by setting the SWDIOTMSPEN and SWCLKTCKPEN bits in GPIO ROUTEPEN to 0.

#### 32.3.4.2.2 JTAG Debug Connection

The JTAG Debug Port is routed as an alternate function and the TMS, TCK, TDO, and TDI pin connections are enabled by default with internal pull up, pull down, no pull, and pull up resistors, respectively. It is possible to disable these pin connections (and disable the pull resistors) by setting the SWDIOTMSPEN, SWCLKTCKPEN, TDOPEN, and TDIPEN bits in GPIO ROUTEPEN to 0.

## 32.3.4.2.3 Disabling Debug Connections

When the debug pins are disabled, the device can no longer be accessed by a debugger. A reset will set the debug pins back to their enabled default state. The GPIO_ROUTEPEN register can only be updated when the debugger is disconnected from the system. Any attempts to modify GPIO_ROUTEPEN when the debugger is connected will not occur. If you do disable the debug pins, make sure you have at least a 3 second timeout at the start of your program code before you disable the debug pins. This way the debugger will have time to connect to the the device after a reset and before the pins are disabled.

### 32.3.4.2.4 ETM Trace Connections

There are five trace pins available on the device. One trace clock which can be enabled by setting the ETMTCLKPEN bitfield in GPIO_ROUTEPEN. The four data pins can be enabled individually by setting ETMTD0PEN, ETMTD1PEN, ETMTD2PEN and ETMTD3PEN respectively in GPIO_ROUTEPEN. It is possible to choose which pins the trace data will be exported to. The lowest trace bit will be routed to the first enabled trace pin. For example, if the ETM data port size is 2 bits and TD0 and TD3 are enabled, will make bit 0 be routed to TD0 while bit 1 will be routed to TD3.

Both the TCLK and all the TD pins can also be routed to alternate locations by configuring the ETMLOC bitfield in GPIO_ROUTELOCO.

## 32.3.5 Interrupt Generation

Interrupts may be triggered on edge events for any GPIO pin, or on pin input levels for GPIO capable of EM4 wake-up.

#### 32.3.5.1 Edge Interrupt Generation

The GPIO can generate an interrupt from any edge of the input of any GPIO pin on the device. The edge interrupts have asynchronous sense capability, enabling wake-up from energy modes as low as EM3 Stop, see Figure 32.6 Pin N Interrupt Generation on page 1114.

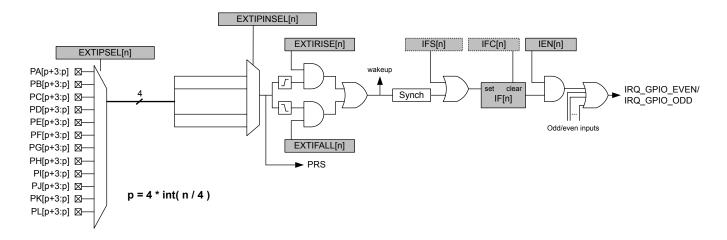

Figure 32.6. Pin N Interrupt Generation

External pin interrupts can be represented in the form of EXTI[index], where index is the external interrupt number. For example, the EXTI7 interrupt has an index of 7. All pins within a group of four (0-3,4-7,8-11,12-15) from all ports are grouped together to trigger one interrupt. The group of pins available to trigger an interrupt is determined by the interrupt index and calculated as int(index/4). For example the first 4 interrupts (EXTI0 - EXTI3) are triggered by pins in the first group (Px[3:0]) and the second 4 interrupts (EXTI4-EXTI7) are triggered by pins in the second group (Px[7:4]).

The EXTIPSELn bits in GPIO_EXTIPSELL or GPIO_EXTIPSELH select which PORT in the group will trigger the interrupt. The EXTI-PINSELn bits in GPIO_EXTIPINSELL or GPIO_EXTIPINSELH will determine which pin inside the selected group will trigger the interrupt.

For example if EXTIPSEL11 = PORTB and EXTPINSEL11 = 0 then PB8 will be used for EXTI11. EXTI11 uses the third group (11/4 = 2) so the list of possible pins is Px[11:8]. The setting of EXTIPSEL11 further narrows the selection to PB[11:8]. Finally EXTPINSEL11 selects the first pin in that group which is PB8.

The GPIO_EXTIRISE[n] and GPIO_EXTIFALL[n] registers enable sensing of rising and falling edges. By setting the EXT[n] bit in GPIO_IEN, a high interrupt flag n, will trigger one of two interrupt lines. The even interrupt line is triggered by any enabled even numbered interrupt flag index, while the odd interrupt line is triggered by odd flag indexes. The interrupt flags can be set and cleared by software when writing the GPIO_IFS and GPIO_IFC registers. Since the external interrupts are asynchronous, they are sensitive to noise. To increase noise tolerance, the MODEL and MODEH fields in the GPIO_Px_MODEL and GPIO_Px_MODEH registers, respectively, should be set to include glitch filtering for pins that have external interrupts enabled.

### 32.3.5.2 Level Interrupt Generation

GPIO can generate a level interrupt using the input of any GPIO EM4 wake-up pins on the device. The interrupts have asynchronous sense capability, enabling wake-up from energy modes as low as EM4.

In order to enable the level interrupt, set the EM4WU field in the GPIO_IEN register and the EM4WUn field in the GPIO_EXTILEVEL register. Upon a level interrupt occuring, the corresponding EM4WU index in the GPIO_IF register will be set along with the odd or even interrupt line depending on the index inside of GPIO_IF. For example, by setting the EM4WU8 in GPIO_EXTILEVEL and EM4WU[8] in GPIO_IEN, the interrupt flag EM4WU[8] in GPIO_IF will be triggered by a high level on pin EM4WU8 and a interrupt request will be sent on IRQ_GPIO_EVEN.

The wake-up granulalrity of the level interrupts is based on the settings of the EM4WU field in the GPIO_IEN register and the EM4WUEN field in the GPIO_EM4WUEN register, see Table 32.3 Level Interrupt Energy Mode Wakeup on page 1115

Table 32.3. Level Interrupt Energy Mode Wakeup

GPIO_IEN	GPIO_EM4WUEN	Energy Mode Wakeup
0	0	No Interrupt
0	1	EM4H,EM4S
1	0	EM1,EM2,EM3,EM4H,EM4S
1	1	EM1,EM2,EM3,EM4H,EM4S

### 32.3.6 Output to PRS

All pins within a group of four(0-3,4-7,8-11,12-15) from all ports are grouped together to form one PRS producer which outputs to the PRS. The pin from which the output should be taken is selected in the same fashion as the edge interrupts.

PRS output is not affected by the interrupt edge detection logic or gated by the IEN bits. See Figure 32.6 Pin N Interrupt Generation on page 1114 for an illustration of where the PRS output signal is generated.

### 32.3.7 Synchronization

To avoid metastability in synchronous logic connected to the pins, all inputs are synchronized with double flip-flops. The flip-flops for the input data run on the HFBUSCLK. Consequently, when a pin changes state, the change will have propagated to GPIO_Px_DIN after two 2 HFBUSCLK cycles. Synchronization (also running on the HFBUSCLK) is also added for interrupt input. To save power when the external interrupts or level interrupts are not used, the synchronization flip-flops for these can be turned off by clearing INT or EM4WU,respectively, in GPIO_INSENSE register.

# 32.4 Register Map

The offset register address is relative to the registers base address.

Offset	Name	Туре	Description

### 32.5 Register Description

# 32.5.1 GPIO_Px_CTRL - Port Control Register

Offset			Bit Position
0x000	30 30 29 27 28 28 28	2 23 24 25 25 25 25 25 25 25 25 25 25 25 25 25	00 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
Reset	0	0x5	0 0 0 0 0
Access	Z X	RW	NA NA NA NA NA NA NA NA NA NA NA NA NA N
Name	DINDISALT	SLEWRATEALT	DRIVESTRENGTHALT  DINDIS  SLEWRATE  DRIVESTRENGTH
Bit	Name	Reset Acc	cess Description
31:29	Reserved	To ensure compatib	ibility with future devices, always write bits to 0. More information in 1.2 Conven-
28	DINDISALT	0 RW	V Alternate Data in Disable
	Data input disable fo	r port pins using altern	nate modes.
27:23	Reserved	To ensure compatib	ibility with future devices, always write bits to 0. More information in 1.2 Conven-
22:20	SLEWRATEALT	0x5 RW	Alternate Slewrate Limit for Port
	Slewrate limit for por	t pins using alternate r	modes. Higher values represent faster slewrates.
19:17	Reserved	To ensure compatib tions	ibility with future devices, always write bits to 0. More information in 1.2 Conven-
16	DRIVESTRENGTH- ALT	0 RW	V Alternate Drive Strength for Port
	Drive strength setting	g for port pins using alt	Iternate drive strength.
	Value	Mode	Description
	0	STRONG	10 mA drive current
	1	WEAK	1 mA drive current
15:13	Reserved	To ensure compatible tions	ibility with future devices, always write bits to 0. More information in 1.2 Conven-
12	DINDIS	0 RW	V Data in Disable
	Data input disable fo	r port pins not using al	alternate modes.
11:7	Reserved	To ensure compatibutions	ibility with future devices, always write bits to 0. More information in 1.2 Conven-
6:4	SLEWRATE	0x5 RW	Slewrate Limit for Port
	Slewrate limit for por		ate modes. Higher values represent faster slewrates.
3:1	Reserved	To ensure compatible tions	ibility with future devices, always write bits to 0. More information in 1.2 Conven-

Bit	Name	Reset Acc		Description								
0	DRIVESTRENGTH	0	RW	Drive Strength for Port								
	Drive strength setting	for port pins no	ot using alte	e modes.								
	Value	Mode		Description								
		0==00		40 4 1:								
	0	STRONG		10 mA drive current								
	0 1	WEAK		1 mA drive current  1 mA drive current

## 33. APORT - Analog Port

#### **Quick Facts**

#### What?

The Analog Port (APORT) is a set of analog buses which are used to connect I/O pins to analog peripheral signals.

### Why?

The APORT gives on-chip analog resources access to a large number of I/O pins, and provides the system designer with a high degree of routing flexibility.

#### How?

An analog peripheral requests a pad by simply configuring its input/output to use a channel on APORT. That selection becomes an APORT request where the APORT control switches the pad and the analog signal onto a common bus.

### 33.1 Introduction

APORT consists of wires, switches, and control logic needed to route signals between analog peripherals and I/O pins. On-chip clients can be either producers or consumers. Analog producers are active devices that drive current/voltage into an APORT, such as current or voltage DACs. Consumers are passive devices that monitor or react to the current/voltage routed to them via the APORT, such as ADCs or analog comparators (ACMP).

### 33.2 Features

- Pins are typically mapped to two different APORT buses
- Arbitration and conflict status provided to each APORT client

## 33.3 Functional Description

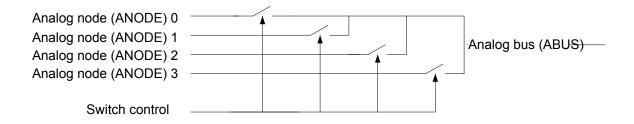

Figure 33.1. Analog Bus (ABUS)

An analog bus (ABUS) consists of analog switches connected to a common wire as shown in Figure 33.1 Analog Bus (ABUS) on page 1156. An APORT consists of multiple ABUSes. Since many clients can operate differentially, buses are grouped by pairs as X and Y. If a given client uses a single ABUS (e.g. single-ended ADC), X and Y are just labels to differentiate the two buses.

When operating differentially, most APORT clients require that one input be chosen from an X bus and the other from a Y bus. For example, the ACMP block will not allow both positive and negative inputs to be chosen from X buses.

#### 33.3.1 I/O Pin Considerations

For external analog signals routed through the APORT, the maximum supported analog I/O voltage will typically be limited to the MIN(V_{ANALOGSUPPLY}, IOVDD) (where V_{ANALOGSUPPLY} is the supply pin powering the analog module). Practically, this means that if IOVDD=1.8 V, the maximum supported analog IO voltage on APORT-routed signals will be limited to 1.8 V, regardless of the analog module supply voltage.

### 33.3.2 APORT ABUS Naming

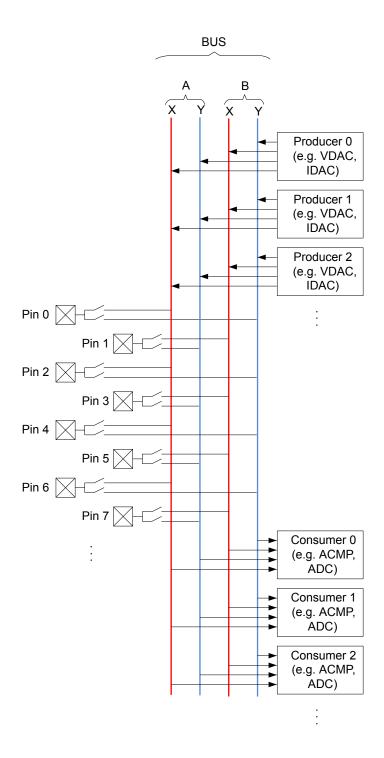

Figure 33.2. Conceptual APORT Structure

APORT ABUSes are prefixed with "BUS" and are grouped in pairs. Each pair is uniquely identified using a letter prefix ("A", "B", "C", etc.) followed by either a "X" or "Y" to identify the ABUS in the pair. For example, "BUSDX" decodes as: "BUS"=ABUS, "D"=pair, "X"=bus. Figure 33.2 Conceptual APORT Structure on page 1157 illustrates this organization.

APORT clients are generally described once in this reference manual regardless of its number of instances. For example, the ACMP client is described once, but the device could contain multiple instances of the ACMP. Because of this, for APORT client descriptions in this reference manual, the ABUS connections are generalized with the prefix "APORT" followed by a number (instead of the "BUS"

followed by a letter). It is possible that different instances of an APORT client connect to different ABUSes. For example, ACMPO APORT1X might connect to the ABUS BUSAX while ACMP1 APORT1X might connect to ABUS BUSCX. Refer to the APORT Client Map in the device data sheet to map the generalized APORT client bus name to an actual device ABUS. A given ABUS has multiple switches which need to be identified. The switches on a bus are specified with the ABUS connection ID followed by a channel ID. For example, channel switch 7 on a given APORT client might be given as APORT1XCH7. Not all APORT channels map to actual GPIO. Refer to the APORT Client Maps in the device data sheet for APORT to GPIO mapping.

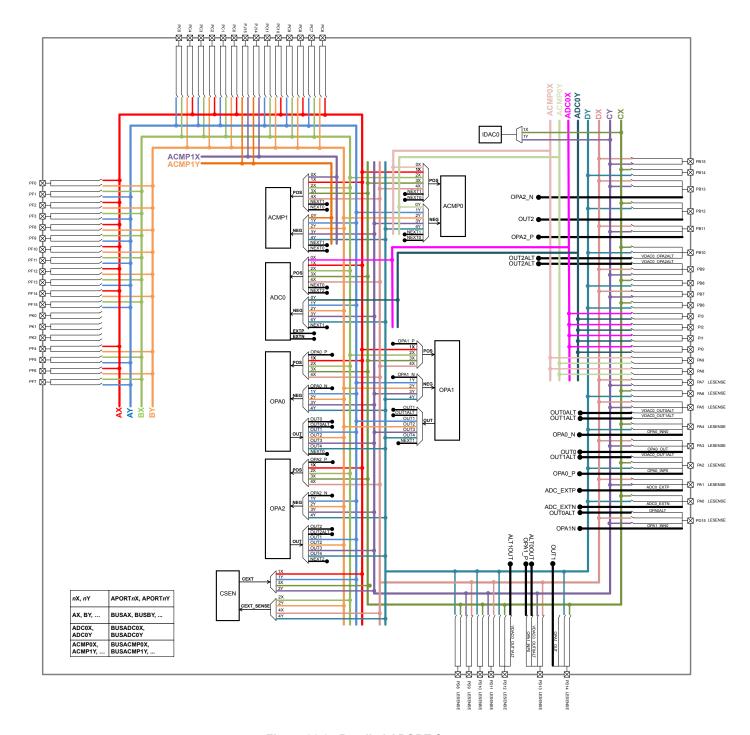

Figure 33.3. Detailed APORT Structure

Figure 33.3 Detailed APORT Structure on page 1158 shows all the possible routes between different peripherals and different pins via APORT BUS for the largest package of the EFR32 device family. Note that, in the figure, the BUSxX and BUSxY are annotated as xX and xY, where x=A,B,C,D and the APORTnX and APORTnY are annotated as nX and nY, where n=1,2,3,4.

For example, the IDAC APORT output 1X can be routed to pin PB14 through BUSCX. The configuration required for this routing is as follows:

- Set IDAC_CTRL_APORTOUTSEL = APORT1XCH30. This selects the IDAC APORT output 1X and pin PB14.
- Set IDAC_CTRL_APORTOUTEN = 1 and IDAC_CTRL_APORTOUTENPRS = 0. This enables the IDAC to ungate it's output to BUSCX.

Another example, when ADC is configured to operate in single channel mode for differential inputs (see 26.3.3.1 Single Channel Mode for how to configure ADC in single channel mode), the positive ADC APORT input 2X and the negative ADC APORT input 2Y can be routed to pin PC9 and PC10 via BUSBX and BUSBY respectively with the following configuration:

- Set ADCn_SINGLECTRL_POSSEL = APORT2XCH9. This selects the pin PC9 for the positive input to the ADC.
- Set ADCn_SINGLECTRL_NEGSEL = APORT2YCH10. This selects the pin PC10 for the negative input to the ADC.

For smaller packages, not all GPIO pins are available. See the pinout sections of the device data sheet for pin availability on a specific device.

### 33.3.3 Managing ABUSes

The ABUSes of an APORT are shared resources. The user needs to be mindful of this in assigning I/O for different clients throughout the chip, as it is possible to have conflicts for a given ABUS. Each ABUS has an arbiter responsible for limiting the control over the ABUS to one and only one client. If multiple clients attempt to control an ABUS, the arbiter allows no client control over the ABUS and asserts a conflict signal to the clients. The user has the ability to check for such a conflict in each client's status, as well as generate an interrupt.

Having only one client control an ABUS is not the same as having only one user of an ABUS. It is possible for multiple clients to access a single ABUS, but requires all but one client to relinquish control of the ABUS. To do this, some clients have bits to disable bus mastership which are 0 by default. One example is the APORTXMASTERDIS bit in the ACMPn_CTRL. When set to 1, the client will not assert control of the APORT X BUS switches, but may still connect to an APORT X BUS that is controlled by another client.

For example, the ADC and ACMP both want to use the same pin on a particular ABUS the user might set the bus master disable bit to 1 for the ACMP. The ADC is the sole master of the switch configuration on that ABUS, so switches are configured using the configuration set in the ADC. When the ACMP channel is chosen on that same bus, the actual pin connection is dictated by the ADC settings for that bus.

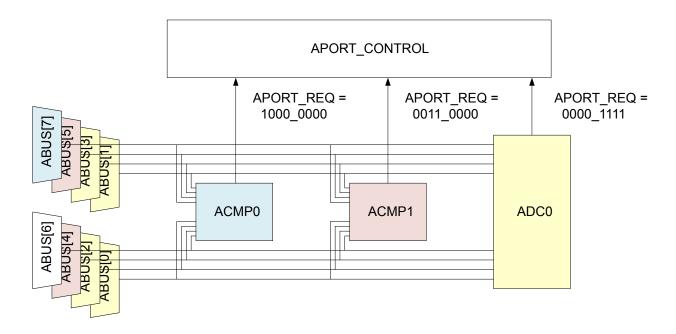

Figure 33.4. APORT Example 1

Figure 33.4 APORT Example 1 on page 1160 illustrates the sharing of APORT. For illustration purposes, each ABUS is identified by a numeric index (instead of BUSAX, BUSAY, BUSBX, etc.). Also, the requests from all the APORT clients are packed into a bit-vector named APORT_REQ to illustrate the request from the APORT Clients (instead of by name such as APORT1XREQ, APORT1YREQ, APORT2XREQ, etc.). In Figure 33.4 APORT Example 1 on page 1160, ABUS and client are the same color if the client has been granted the ABUS.

In Figure 33.4 APORT Example 1 on page 1160 ADC0 has requested ABUS[3:0], ACMP1 has requested ABUS[5:4], ACMP0 has requested ABUS[7], and ABUS[6] is unused. No APORT Client has requested the same ABUS as another, so there is no conflict.

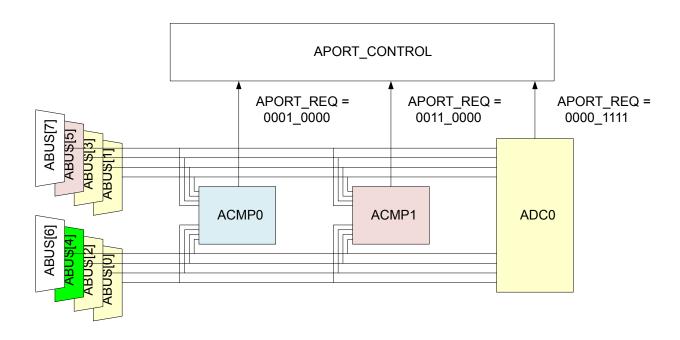

Figure 33.5. APORT Example 2: Bus Conflict

In Figure 33.5 APORT Example 2: Bus Conflict on page 1161 is a similar example to Figure 33.4 APORT Example 1 on page 1160, but now both ACMP0 and ACMP1 are requesting ABUS[4]. This is a configuration error, so APORT grants neither client ABUS[4]. The user must resolve the conflict before ABUS[4] is useable.

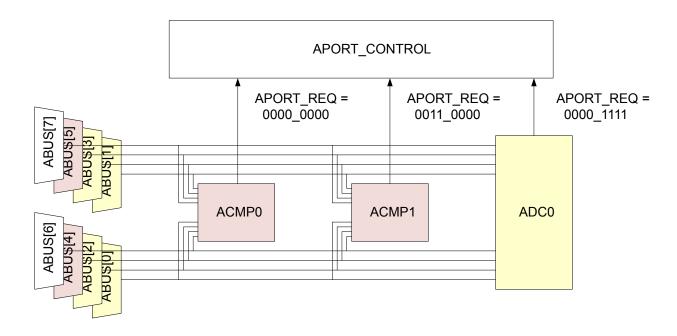

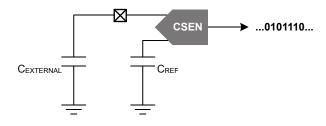

Figure 33.6. APORT Example 3: Sharing an ABUS

Figure 33.6 APORT Example 3: Sharing an ABUS on page 1161 illustrates ABUS sharing. Both ACMPs are configured identically, except ACMP0 has its APORTXMASTERDIS bit-field set to 1. There is only one APORT master for ABUS[5:4] in this case, so there is no conflict.

## 34. CSEN - Capacitive Sense Module

#### **Quick Facts**

#### What?

The capacitive sense (CSEN) module uses a capacitance-to-digital circuit to measure the capacitance of touch-sensitive switches. The module contains an advanced capacitance-to-digital converter that can be configured to take measurements on a single port pin or scan through a group of up to 64 port pins connected via the APORT buses. Port pins/channels can also be shorted together internally to measure the combined capacitance, lowering the required energy usage for wake-on-touch applications. Adjustable maximum capacitance allows for optimal dynamic range, while hardware accumulation and filtering reduce processor computation time. Interrupts can be generated when CSEN completes conversions or when the measured value crosses a threshold.

## Why?

The CSEN module is designed to perform extremely low-power autonomous conversions of capacitive touch switches.

### How?

The CSEN module uses charge timing techniques to compare external capacitance against internal reference capacitors.

## 34.1 Introduction

The capacitive sensing (CSEN) module uses a capacitance-to-digital circuit to determine the capacitance on an input pin. The module can take measurements from different physical pins using the APORT multiplexer. In addition, the module can measure multiple pins in sequence using the scan modes, or multiple pins at the same time (bonded together) using the multiple-channel measurement feature. CSEN is available in EM0, EM1, EM2 and EM3.

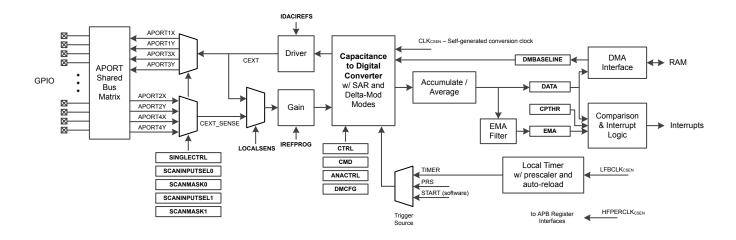

Figure 34.1. CSEN Overview

#### 34.2 Features

- · Up to 64 Channels, connected via APORT buses.
- · Single sample, continuous single sample, single scan and continuous scan modes supported.
- Support for both SAR and Delta Modulation conversions.
  - SAR conversions are programmable to resolutions of 10, 12, 14, or 16 bits.
  - Delta Modulation conversions support dynamic or fixed gain, and are programmable to resolutions of 10, 12, 14, or 16 bits.
- Supports channel bonding to monitor multiple channels, shorted internally, with a single conversion. The maximum number of channels to be shorted is limited by the maximum capacitance that can be measured by the analog core.
- Conversions triggered by software, PRS, or dedicated timer running from LFXO, LFRCO, or ULFRCO.
- Hardware accumulation of 1, 2, 4, 8, 16, 32, or 64 samples. The result can be right-shifted to the desired resolution or collected in a 22-bit accumulator for further processing by software.
- Hardware exponential moving average (EMA) filter for candidate touch detection during low power autonomous operation.
- · Automatic threshold comparison with programmable polarity.
- Low-frequency noise filter to reject noise sources such as 50/60 Hz.
- DMA interface to collect accumulated samples in on-chip RAM. The DMA interface can also be used to program starting values for delta-modulation conversions. The DMA interface can run down to EM2.

#### 34.3 Timing

Conversion timing for the CSEN block is flexible, with access to several clocks and conversion trigger sources.

#### 34.3.1 Clocks

The CSEN module takes two external clock sources as input. The register interface is driven by the HFPERCLK source, allowing for fast access to the control and data for the block. The local timer is driven by the LFBCLK source. The CSEN block also contains an internal, low-energy conversion clock source (CLK_{CSEN}). Conversions are self-timed and the block only requires external clocks under certain circumstances.

For register access, HFPERCLK_{CSEN} must be enabled to the CSEN block in the CMU_HFPERCLKEN0 register. When register access is not required, this clock may be shut down for energy savings.

LFBCLK_{CSEN} is used by the local CSEN timer. It should be enabled to the CSEN block in the CMU_LFBCLKEN0 register any time the CSEN local timer is used as a conversion trigger.

## 34.3.2 Conversion Triggers

CSEN conversions can be triggered from one of three different sources, selected by CTRL_STM: a software register write, a PRS channel, or the local CSEN timer. The selected trigger source begins a conversion cycle. Depending on the selected conversion mode, one conversion trigger may generate one or many output words from the CSEN module. See 34.6 Converison Modes for more details on the CSEN output for each mode.

#### **Software Triggered Conversions**

When CTRL_STM is set to START, conversions are triggered by software. Software triggering is typically used when operating the CSEN block in a continuous mode to gather conversions as quickly as the converter allows. Software triggering may also be used in applications where a single conversion or one scan cycle is needed infrequently and sporadically by different software processes. When configured for software triggering, a write of the CMD_START bit to logic 1 initiates conversions.

## **PRS Triggered Conversions**

When CTRL_STM is set to PRS, conversions are triggered via a PRS event. PRS triggers are typically used when it is necessary to synchronize CSEN conversions with other events in the system. For example, the LETIMER may be used in EM2 to initiate a CSEN scan operation and other events at the same time. A number of different PRS channels may be configured as the trigger source. The specific PRS channel to be used as a trigger source is selected in the PRSSEL register.

### **CSEN Timer Triggered Conversions**

When CTRL_STM is set to TIMER, a local 8-bit CSEN timer is used to trigger conversions. The local timer is typically used in conjunction with non-continuous conversion modes to provide periodic conversion triggers at slow sampling rates. The local timer is clocked from LFBCLK_{CSEN}, and configured with the TIMCTRL register. The CSEN timer has a local prescaler (set by the TIMCTRL_PCPRESC field), which divides the LFBCLK_{CSEN} further. The TIMCTRL_PCTOP field sets the reload value for the CSEN timer. The CSEN timer counts down for the number of clocks specified in TIMCTRL_PCTOP. When the counter reaches zero, a conversion cycle is triggered and the timer is reloaded.

## 34.3.3 Shutdown and Warmup

Many target applications for CSEN require low power operation and infrequent sampling. By default, the converter will power down when it is not in use to save energy. Upon receiving a conversion trigger, the CSEN block will power on and wait for (3 + TIMCTRL_WARMPCNT) CLK_{CSEN} clock cycles before starting conversions.

CTRL_WARMUPMODE defines the behavior of the CSEN converter when it is not actively converting. Software may choose to keep the CSEN block powered on at all times by setting the CTRL_WARMUPMODE bit to logic 1.

#### 34.4 Conversion Types

The CSEN block offers two different types of conversions: SAR, and Delta Modulation.

#### 34.4.1 SAR Conversion Type

SAR (successive approximation register) conversions are self-contained and do not depend on the results of any previous conversions. SAR conversions will be performed when CTRL_CONVSEL is set to SAR. CTRL_SARCR sets the SAR conversion resolution, and is selectable between 10, 12, 14, or 16 bits. SAR conversions last for N cycles of CLK_{CSEN}, where N is the selected resolution (i.e. 12-bit conversions last for 12 CLK_{CSEN} cycles).

Every SAR conversion consists of a set of tests, one for each bit of the converter. The MSB is tested first, followed by all other bits down to the LSB. Each test narrows the possible value by 1/2 until the final result is determined.

#### 34.4.2 Delta Modulation Conversion Type

Delta modulation (DM) conversions provide significant noise, response time, and energy consumption improvements over SAR conversions. A DM conversion inherently takes longer than a SAR conversion to arrive at one result. However, it is much less susceptible to noise events in the system. Whereas a large number of SAR conversions may need to be averaged to produce a desired noise resolution, the same noise resolution can be achieved with few DM conversions. However, DM conversions require more specific knowledge of the underlying conversion process to implement effectively. Silicon Laboratories software libraries use delta modulation for the best possible performance. It is recommended to use the provided libraries in most applications. The information provided in this section is intended as a reference for CSEN module driver development.

Delta modulation conversions are performed when CTRL_CONVSEL is set to DM. DMCFG_DMCR sets the DM conversion resolution, and is selectable between 10, 12, 14, or 16 bits. The selected resolution does not have an impact on conversion timing.

A delta modulated conversion begins with a test against a provided initial value, known as the baseline. If the comparison is high (the external capacitor is larger than the initial value), the comparison value is increased by a specified amount (the delta). If the comparison is low, the comparison value is decreased by the delta. The cycle then repeats, testing against the new value. Each subsequent test brings the test value closer to the external capacitance value, until the desired number of tests have been performed and an output result is produced. The converter may be configured to use a fixed delta value, or to reduce the value by a factor of two at specific intervals.

The DM state machine is configured using different fields in the DMCFG register. The DMG field sets the initial delta step to be used, between 0 and 255 codes at the selected resolution (specified by DMCFG_CRMODE). The DMCFG_DMR field specifies how many tests in a row are to be performed using each delta step. The converter will perform (4 x DMCFG_DMR) tests at each delta step for DMCFG_DMR > 0. For DMCFG_DMR = 0, the converter will perform 64 tests at each delta step. The number of tests performed at each delta step is referred to here as a "cycle". The DMCFG_DMCR field specifies how many cycles the state machine will take to produce one conversion output. For DMCFG_DMCR = 0, the number of cycles will be 16. If the DMCFG_DMGRDIS bit is cleared to 0, the delta step will be halved after each cycle. If DMCFG_DMGRDIS is set to 1, all cycles will use a fixed delta step value. Each test performed by the converter requires one CLK_{CSEN}, and so a full DM conversion requires number_of_cycles x tests_per_cycle clocks of CLK_{CSEN}. Figure 34.2 Delta Modulation Conversion With Gain Reduction (DMCFG_DMGDIS = 0) on page 1165 and Figure 34.3 Delta Modulation Conversion With Fixed Delta Step (DMCFG_DMGDIS = 1) on page 1166 show how delta modulation conversions are performed with and without gain reduction.

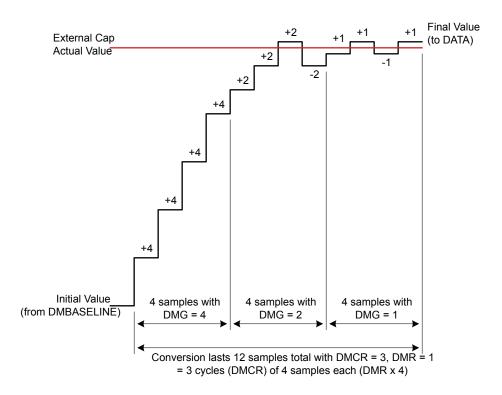

Figure 34.2. Delta Modulation Conversion With Gain Reduction (DMCFG_DMGDIS = 0)

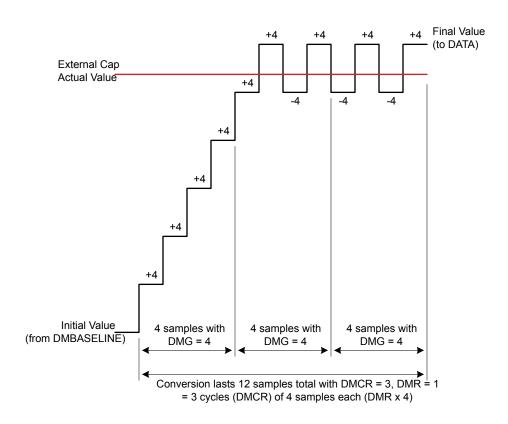

Figure 34.3. Delta Modulation Conversion With Fixed Delta Step (DMCFG_DMGDIS = 1)

The initial test value (baseline) for a DM conversion can be written to the DMBASELINE register prior to the start of the conversion. DMBASELINE contains two fields: BASELINEUP and BASELINEDN. Only the BASELINEUP field is used when chopping is disabled (CTRL_CHOPEN = 0). If chopping is enabled, software must maintain a second baseline value for the ramp-down phase, and write it to BASELINEDN.

#### 34.5 Input Configuration

CSEN channel inputs are routed through the on-chip APORT bus matrix. Each APORT bus is a shared resource among certain analog peripherals on the device. Some knowledge of how the CSEN block utilizes the APORT buses is necessary to avoid conflicts with other peripherals.

Each time the CSEN module connects to an external pin to take a conversion, it uses one or two of the shared APORT buses. By default, the CSEN module charges the external capacitor through one APORT connection on the CEXT line, and senses the voltage at the capacitor through a different APORT connection on the CEXT_SENSE line. This eliminates any errors introduced by series impedance of the APORT buses, particularly if the external cpacitance is large. To conserve on-chip resources, it is possible to both charge and sense through the CEXT line, by setting CTRL_LOCALSENS to logic 1.When CTRL_LOCALSENS is set to 1, the CEXT_SENSE line is not needed and the corresponding bus may be used by other peripherals.

The CSEN module has four APORT buses connected to the CEXT signal and four APORT buses connected to the CEXT_SENSE signal. The specific buses used for each pin selection depend on the channel, according to Table 34.1 CSEN APORT Bus Connectivity on page 1167. For example, if APORT1XCH4 (APORT1 channel 4) is selected in SINGLECTRL_SINGLESEL, the CEXT signal will be connected to the shared BUSAX, channel 4. If CTRL_LOCALSENS is set to DISABLE, then the CEXT_SENSE signal will be connected to APORT2YCH4, and use the shared bus BUSBY, channel 4.

The same connections apply to scan mode conversions and bonded conversions. For scan mode conversions, the connection through the bus is only made on one channel at a time, when that channel is being converted in the scan. For bonded connections, all selected channel connections are made simultaneously.

Selected CSEN Channel	CEXT Routing	CEXT_SENSE Routing
		(LOCALSENS = 0)
APORT1, Even Channel	APORT1XCHn / BUSAXCHn	APORT2YCHn / BUSBYCHn
APORT1, Odd Channel	APORT1YCHn / BUSAYCHn	APORT2XCHn / BUSBXCHn
APORT3, Even Channel	APORT3XCHn / BUSCXCHn	APORT4YCHn / BUSDYCHn
APORT3, Odd Channel	APORT3YCHn / BUSCYCHn	APORT4XCHn / BUSDXCHn

Table 34.1. CSEN APORT Bus Connectivity

When the CSEN module requests an APORT bus that is already in use by another peripheral, an APORT conflict will occur. The IF_APORTCONFLICT interrupt flag will be set to 1 (generating an interrupt if enabled), and the APORTCONFLICT register will reflect the bus(es) where the conflict occurred. Careful channel planning for the system will avoid APORT conflicts in most systems.

Channel selection for the CSEN module depends on the selected conversion mode. More details on how to select specific input pins are found in 34.6 Conversion Modes.

#### 34.6 Converison Modes

The CSEN module supports several conversion modes:

- Single Channel A conversion trigger starts conversions on a single channel. One output result is produced, then the converter will halt.
- Scan A conversion trigger starts a scan sequence, which converts a specified number of channels independently and in sequence.
   One output result is produced per channel, then the converter will halt.
- Bonded Channel A conversion trigger starts conversions on a bonded channel. A bonded channel is several input channels which are shorted together internally. One output result is produced, then the converter will halt.
- Continuous Single Channel A conversion trigger starts continuous conversions on a single channel. The single channel conversion
  will re-trigger automatically after each output result and repeat until halted.
- Continuous Scan A conversion trigger starts continuous channel scanning. The scan sequence will re-trigger automatically at the
  end of each scan and repeat until halted.
- Continuous Bonded Channel A conversion trigger starts continuous conversions on a bonded channel. The bonded channel conversion will re-trigger automatically after each output result and repeat until halted.

The conversion mode is selected by the CTRL_CM and CTRL_MCEN fields. Refer to 34.6.1 Single Channel Conversions, 34.6.2 Scan Conversions, and 34.6.3 Bonded Channel Conversions for specific information on configuring the CSEN module to the desired conversion mode.

## 34.6.1 Single Channel Conversions

CSEN is configured for single channel mode when CTRL_MCEN = DISABLE and CTRL_CM = SGL. For continuous single channel mode, CTRL_MCEN = DISABLE and CTRL_CM = CONTSGL.

In single channel mode, SINGLECTRL_SINGLESEL specifies the input channel to be converted. Firmware may select any of the pins connected to the CEXT signal via the APORT. Refer to the Analog Port (APORT) Client Maps section in the product data sheet for mapping of the CEXT signal to specific pins.

When a single channel conversion is triggered, the CSEN block will use the configured conversion type (SAR or DM) to convert the capacitance seen at the selected input pin to a digital value one or more times. The hardware accumulator setting (CTRL_ACU) determines how many times the input pin will be sampled and accumulated before an output word is produced. The IF_CONV interrupt flag will be set to 1 by hardware when an output word is available in the DATA register.

**Note:** The auto-ground feature is typically not used in single channel conversion mode and should be disabled by software. However, if auto-grounding is enabled, it will ground the unused channels specified by the SCANINPUTSEL0/1 and SCANMASKSEL0/1 registers. See the channel selection discussion in 34.6.2 Scan Conversionsfor more details.

#### 34.6.2 Scan Conversions

CSEN is configured for scan mode when CTRL_MCEN = DISABLE and CTRL_CM = SCAN. For continuous scan mode, CTRL_MCEN = DISABLE and CTRL CM = CONTSCAN.

In scan mode, the input channels to be converted during the scan are determined by the SCANINPUTSEL0/1 and SCANMASK0/1 registers. There are 64 available channels in the scanner logic. SCANINPUTSEL0/1 allow software to route CSEN scan channels to APORT-capable GPIO in groups of 8. SCANMASK0/1 specify which channels on those groups are to be included in the scan.

**Note:** It is possible to include the same group of 8 in more than one place in the scan sequence. However, for the majority of use cases, the SCANINPUTSEL0 register should be written to 0x07060504, and SCANINPUTSEL1 should be written to 0x0F0E0D0C. This will configure the CSEN scan channels to match their order in bonded mode.

Individual channels are included in the scan based on their bit positions in the mask registers, SCANMASK0 and SCANMASK1. A '1' in the corresponding bit of the mask register will include that channel in the scan. Refer to the Analog Port (APORT) Client Maps section in the product data sheet for mapping of the CEXT signal to specific pins.

When a scan conversion is triggered, the CSEN block will convert each of the selected channels in turn, starting at channel 0 and working up to channel 63. If a channel is not configured for scan in the SCANMASKO/1 register (i.e. the bit for that channel is '0'), it will be skipped.

An example of how the scan logic progresses through channels is shown in Figure 34.4 Scan Mode Sequencing on page 1169. In this simple example, SCANMASK0 = 0x000000318 and SCANMASK1 = 0x00000006, which selects channels 3, 4, 8, 9, 33, and 34 in turn.

Figure 34.4. Scan Mode Sequencing

An auto-grounding feature is available for scan mode conversions. This feature forces hardware to ground all of the non-active CSEN channels selected by SCANMASK0/1, to reduce bleed-through from measurements on other CSEN channels. Auto-grounding is enabled by setting the CTRL AUTOGND bit to logic 1.

CSEN will use the configured conversion type (SAR or DM) to convert the capacitance seen at each of the selected input pins to a digital value one or more times. The hardware accumulator setting (CTRL_ACU) determines how many times each input pin will be sampled and accumulated before an output word is produced. The IF_CONV interrupt flag will be set to 1 by hardware when each output word is available in the DATA register, and the IF_EOS interrupt flag will be set to 1 by hardware at the completion of a scan cycle.

The DMBASELINE register provides the starting point for DM conversions. This starting point will be different for each channel in the scan, and the DMBASELINE register should be updated accordingly. This is typically done via DMA.

**Note:** DMA or software must read the output words from the DATA register before completion of the next conversion. New conversions will over-write the DATA register contents.

#### 34.6.3 Bonded Channel Conversions

CSEN is configured for bonded mode when CTRL_MCEN = ENABLE and CTRL_CM = SGL. For continuous bonded mode, CTRL_MCEN = ENABLE and CTRL_CM = CONTSGL.

Bonded channel conversions are intended primarily for wake-on-touch applications where minimal power consupmtion is necessary. Bonded channel conversions operate similar to single channel conversions, except that multiple channels are shorted together and converted as a single capacitance value.

In bonded mode, the channels to be bonded are based on their bit positions in the mask registers SCANMASK0 and SCANMASK1, according to a fixed location, as shown in Figure 34.5 CSEN Input Configuration in Bonded Mode on page 1170. SCANMASK0 selects channels from APORT1 and SCANMASK1 selects channels from APORT3. Even-numbered channels are connected through the X bus, and odd-numbered channels are connected through the Y bus. Channels with a '1' in the corresponding position of SCANMASK0/1 will be shorted together during the conversion and converterd as a single channel. Refer to the Analog Port (APORT) Client Maps section in the product data sheet for mapping of the CEXT signal to specific pins.

Figure 34.5. CSEN Input Configuration in Bonded Mode

When a bonded conversion is triggered, the CSEN block will use the configured conversion type (SAR or DM) to convert the total capacitance seen at the selected input pins to a digital value one or more times. The hardware accumulator setting (CTRL_ACU) determines how many times the input pins will be sampled and accumulated before an output word is produced. The IF_CONV interrupt flag will be set to 1 by hardware when an output word is available in the DATA register.

**Note:** The auto-ground feature should not be used in bonded conversion mode. Software should clear CTRL_AUTOGND to 0 when configuring CSEN for bonded conversions.

#### 34.7 Output Data

Output data from the CSEN module is posted to the DATA register. The data encoding can be affected by several configuration settings.

Figure 34.6 Data Encoding for Different Resolution Settings on page 1171 shows the effect that the resolution settings (CTRL_SARCR for SAR conversions or DMCFG_CRMODE for DM conversions) have on the output word. In this example, only one sample is accumulated. Regardless of the resolution setting, the MSB is always presented in bit position 15.

													(	CSEN	_DA	TA Re	giste	r													
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Figure 34.6. Data Encoding for Different Resolution Settings

A hardware accumulator allows the CSEN block to accumulate multiple samples on the same channel for each conversion data word produced, and automatically right-shift to normalize the data to 16 bits. This is effective as a simple noise filter. The CTRL_ACU field sets the number of samples to be accumulated from 1, 2, 4, 8, 16, 32, or 64 samples. The right-shift operation can optionally be disabled by setting CTRL_DRSF to 1. Figure 34.7 Data Encoding for Different Accumulator Settings on page 1171 shows the effects of the accumulator, with and without right-shifting on the output data word. In this example, the sample resolution is fixed at 12 bits, but the same principles apply to any resolution setting.

Figure 34.7. Data Encoding for Different Accumulator Settings

When the conversion type is delta modulation (CTRL_CONVSEL = DM) and chopping is enabled (CTRL_CHOPEN = ENABLE), this is a special case for the output word. In this case, both the "up" and the "down" portions of the conversion must be stored. The DATA

register will hold the "up" portion in the lower 16 bits and the "down" portion in the upper 16 bits as shown in Figure 34.8 Data Encoding for Delta Modulation With Chopping on page 1172.

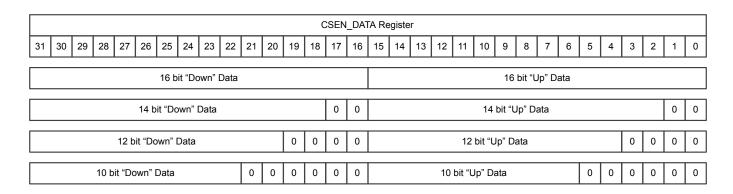

Figure 34.8. Data Encoding for Delta Modulation With Chopping

## 34.8 Low Frequency Noise Filter (Chopping)

The CSEN module includes a low-frequency noise filter, which is implemented internally using a chopping mechanism. Chopping is enabled by setting CTRL_CHOPEN to ENABLE. In a normal conversion cycle (CTRL_CHOPEN = DISABLE), the charge timing is always performed on a positive (up) ramp. When chopping is enabled, the converter will alternate between using a positive (up) and negative (down) ramp for each sample. While the absolute capacitance value contributes the same amount for an up or a down conversion, any low-frequency offset artifacts due to supply changes will have opposite polarity. Averaging the results of an "up" and a "down" conversion taken back-to-back effectively eliminataes the low-frequency offset differences.

When chopping is used with SAR type converisons, the accumulator performs the necessary averaging in hardware. The accumulator must be set to average at least two samples when chopping is enabled. Because the accumulator always works on multiples of two samples, an even number of "up" and "down" samples will be included in the average.

When chopping is used with DM type conversions, user software must maintain both an "up" and "down" portion of the baseline for the conversion separately. For this reason, the output word will contain both values when using DM conversions. In order to gain the benefits of chopping in DM mode, software should average the "up" and "down" results together.

### 34.9 Wake on Threshold and Exponential Moving Average

The CSEN module has the capability to operate in the energy-efficient EM2 or EM3 modes and autonomously wake the system when a predetermined threshold is crossed, either while doing single channel conversions or bonded channel conversions. This allows a system to monitor one or more input channels to implement low-energy "wait-for-touch" features. There are two different comparator threshold tests available for this purpose:

- Absolute used to compare data outputs with "less than or equal" or "greater than" tests against a fixed value. This is useful for applications with short sleep durations, which simply want to wake quickly if a certain condition is met.
- Relative EMA used to compare data outputs against a moving average window. This is extremely useful for applications with long-term sleep requirements. The relative comparison allows the CSEN module to adjust for slow changes in capacitance such as those due to environmental changes (temperature, supply) without waking the system.

The absolute test is used when CTRL_CMPEN = ENABLE and CTRL_EMACMP = DISABLE. In this mode, any output word written to the DATA register will be compared against the value in the CMPTHR register. The polarity of the comparison is configured with the CTRL_CMPPOL field. Setting CTRL_CMPPOL to GT means that the comparison will be true if DATA is greater than CMPTHR. Setting CTRL_CMPPOL to LTE means that the comparison will be true if DATA is less than or equal to CMPTHR. On a true result, the IF_CMP interrupt flag is set to 1, and any continuous conversion in progress will be halted.

The relative EMA test is used when CTRL_EMACMP = ENABLE. In this mode, the exponential moving average (EMA) value is used to establish a low-noise average code reading. The EMA is a moving average that is re-calculated on every output data word from the converter, according to the following equation:

EMA[n] = EMA[n-1] - EMA[n-1]/N + DATA/N,

#### Figure 34.9. CSEN Exponential Moving AverageCalculation

The EMA register stores the current EMA value. This register may be written by software to quickly establish a new baseline average. N in the equation above is the sample weighting of the EMA filter, and is controlled with the EMASAMPLE field. Lower values of EMASAMPLE mean less averaging, and quicker response time, while higher EMASAMPLE values will reject more noise at the expense of response time.

When relative EMA comparisons are enabled, every new sample is compared with a window around the EMA. The lower bound of this window is EMA - CMPTHR, and the upper bound of the window is EMA + CMPTHR. If the new sample written to DATA falls outside that window (lower than the lower bound or higher than the upper bound), the CMP interrupt flag is set to 1 and any continuous conversion in progress is halted. Using the EMA comparison, large jumps in the output data word will trip the comparator and wake the system, but gradual changes will not trigger false positives. Figure 34.10 Wake on Threshold With Relative EMA on page 1174 shows an example of the EMA moving average filter and window.

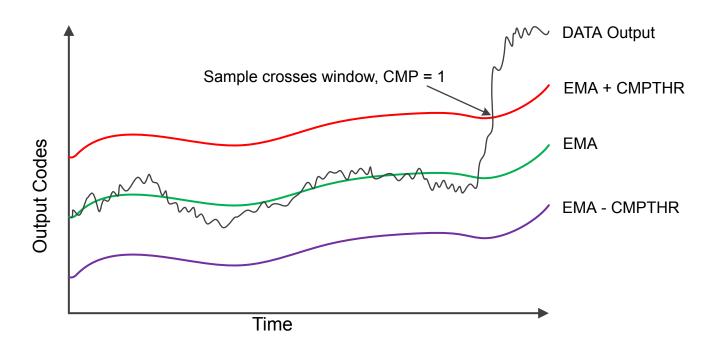

Figure 34.10. Wake on Threshold With Relative EMA

### 34.10 Analog Adjustments

The analog front-end of the CSEN module has some additional controls that may be useful in certain applications.

#### 34.10.1 Current Reference and Gain

The internal current source used for charging the reference capacitor can be adjusted using the ANACTRL_IREFPROG field. This adjusts the ratio of the internal reference current source vs. the external drive current source, and thereby adjusts the effective gain of the converter. The lowest gain setting is when ANACTRL_IREFPROG = 0, and the highest is with ANACTRL_IREFPROG = 7. The difference between the lowest and highest setting is approximately 10x. High gain gives the best sensitivity and resolution for small capacitors, such as those typically implemented as touch-sensitive PCB features. Lower gain allows for larger capacitor values to be measured. It can also be useful to lower the gain when performing bonded channel conversions.

## 34.10.2 Current Drive

The external capacitor is charged with a current-source DAC during conversions. The full scale output of the current DAC can be adjusted using the ANACTRL_IDACIREFS field. When ANACTRL_IDACIREFS is 0, the drive current is at its maximum setting. For ANACTRL_IDACIREFS settings of 1-7, the drive current is reduced by a factor of ANACTRL_IDACIREFS / 8. For most touch switch applications, the maximum (default) current drive (ANACTRL_IDACIREFS = 0) should be used. Lower current drive may be useful when there is additional series impedance between the device pin and the capacitive sensor.

### 34.10.3 Reset (Discharge) Timing

During a conversion, the external capacitance is charged and discharged multiple times. The amount of time used for the reset (discharge) phase is controlled by the ANACTRL_TRSTPROG field. For most touch sensitive switch applications, the fastest (default) timing should be used. Extended reset timing may be useful in applications with additional series impedance between the device pin and the capacitive sensor.

#### 34.11 DMA Interface

The CSEN module has DMA support for reads of the DATA register and writes to the DMBASELINE register. This enables the CSEN module to operate autonomously from software, either to free up software cycles during EM0 or to enable lower power operation in EM1 and EM2.

DMA transfers to and from the CSEN module are enabled by setting the CTRL_DMAEN bit to 1. If the converter is used in SAR mode, only DMA reads (from the DATA register) are triggered. If the converter is used in delta modulation mode, both DMA reads from the DATA register and DMA writes to the DMBASELINE register are triggered.

Requests for a DATA register read occur at the end of a conversion cycle any time the CSEN module writes new output information to the DATA register. DMA may read half words (16 bits) or full words (32 bits) from the DATA register, depending on the specific CSEN configuration and the needs of the application. The CSEN module does not halt when the DMA read request is posted. It will immediately begin the next conversion. If the DMA read request is not serviced by the time the next conversion has completed, the IF_DMAOF flag will be set to indicate an overflow event has occurred.

Requests for a data write to the DMBASELINE register occur only when using delta-modulation type conversions. The write request will be triggered at the start of a conversion, prior to the first sample comparison. The conversion will not begin until the DMA services this write request.

**Note:** If an absolute or EMA threshold interrupt is enabled when using the DMA, software must be aware that the converter will halt when the interrupt condition occurs. In this case it may be necessary to reconfigure portions of the DMA transfer before resuming conversions.

## 34.12 Register Map

The offset register address is relative to the registers base address.

Offset	Name	Туре	Description

5:4	СМ	0x0 RW	CSEN Conversion Mode Select
	This field is used	to select a conversion metho	d.
	Value	Mode	Description
	0	SGL	Single Channel Mode: One conversion of a single channel (when MCE = 0) or set of bonded channels (when MCE = 1) per conversion trigger.
	1	SCAN	Scan Mode: Scans multiple selected channels once per conversion trigger.
	2	CONTSGL	Continuous Single Channel: Continuous conversion of a single channel (when MCE = 0) or set of bonded channels (when MCE = 1).
	3	CONTSCAN	Continuous Scan Mode: Continuously scans multiple selected channels.
3	Reserved	To ensure compatibility tions	with future devices, always write bits to 0. More information in 1.2 Conven-
2	CMPPOL	0 RW	CSEN Digital Comparator Polarity Select
	This bit determin	es the polarity of the digital co	omparator.
	Value	Mode	Description
	0	GT	The digital comparator flag (CMPIF) is set if the conversion result is greater than the threshold.
	1	LTE	The digital comparator flag (CMPIF) is set if the conversion result is less than or equal to the threshold.
1	EN	0 RW	CSEN Enable
			I module can be configured while disabled and then enabled when conver- ncel any conversions in progress, but does not reset the configuration.
	Value	Mode	Description
	0	DISABLE	CSEN disabled.
	1	ENABLE	CSEN enabled and ready to convert. Must be done before the start trigger.
0	Reserved	To ensure compatibility	with future devices, always write bits to 0. More information in 1.2 Conven-

Access		R&																														
Name																SCANINPUTEN																

Bit	Name	Reset	Access	Description
31:0	SCANINPUTEN	0x00000000	RW	Scan Channel Mask

Scan channel mask for CSEN channels CSEN_INPUT0 through CSEN_INPUT31. For scan mode conversions, a '1' in any bit position will include the channel specified by SCANINPUTSEL0 in a scan. For bonded channel conversions, a '1' in any bit position includes the corresponding channel from APORT1 / BUSA in the bonded conversion. If AUTOGND = ENABLE the scan mask also determines the pins that will be grounded when inactive, for both scan and single channel conversions.

31:0 SCANINPUTEN 0x00000000 RW Scan Channel Mask.

Scan channel mask for CSEN channels CSEN_INPUT32 through CSEN_INPUT63. For scan mode conversions, a '1' in any bit position will include the channel specified by SCANINPUTSEL1 in a scan. For bonded channel conversions, a '1' in any bit position includes the corresponding channel from APORT3 / BUSC in the bonded conversion. If AUTOGND = ENABLE the scan mask also determines the pins that will be grounded when inactive, for both scan and single channel conversions.

15:0	CMPTHR	0x0000	RW	Comparator Threshold.

When CMPEN is set to 1 and EMACMPEN is cleared to 0, a greater than or less than/equal (based on CMPPOL) comparison between the DATA register and CMPTHR value. If the desired condition is met, the CMPIF flag will be set. When EMACMPEN is set to 1, a comparison window is used instead. The DATA register will be compared against EMA +/-CMPTHR. The CMPIF flag is set any time the conversion result is above (EMA + CMPTHR) or below (EMA - CMPTHR).

21:0	EMA	0x000000 R	RWH	Calculated Exponential Moving Average

This register contains the current exponential moving average. The EMA is updated every time an accumulated sample is produced, according to the formula: EMA[n] = EMA[n-1] - EMA[n-1]/N + DATA/N, where N is the EMA sample weight selected by EMASAMPLE. This register can be written to initialize the average.

### 35. FPUEH - Floating Point Unit Exception Handler

#### **Quick Facts**

### What?

FPU exception handler allows user defined handling of FPU exceptions.

### Why?

Proper handling of exceptions is crucial in many applications.

#### How?

The FPU exception handler monitors status flags from the FPU and issues an interrupt when exceptions occur.

### 35.1 Functional Description

The Floating Point Unit, FPU, included in the Cortex-M4 has a set of status flags indicating mathematical errors that cause floating-point exceptions. Available status flags are:

- · FPIOC FPU invalid operation.
- · FPDZC FPU divide-by-zero exception.
- · FPUFC FPU underflow exception.
- · FPOFC FPU overflow exception.
- · FPIDC FPU input denormal exception.
- · FPIXC FPU inexact exception.

Refer to the ARM Cortex-M4 Devices Generic User Guide for more information about the FPU status flags. The FPU exception handler, FPUEH, monitors these status flags and sets the corresponding interrupt flag in FPUEH_IF when they are asserted. An interrupt request will be set if the corresponding bit in FPUEH_IEN is set. The interrupt flags can also be set and cleared using the FPUEH_IFS and FPUEH_IFC registers, respectively.

**Note:** Before the FPUEH interrupt flags can be cleared, the corresponding status flag in the FPU has to be cleared. Refer to ARM Cortex-M4 Devices Generic User Guide for information on how to do this.

### 35.2 Register Map

The offset register address is relative to the registers base address.

### 36. Revision History

#### **Revision 1.3**

July, 2022

- Changed incorrect SysTick resolution from 32 to 24 bits in 2.16 Timers.
- User guide references in 7.3.4 Bootloader updated to reflect specific Gecko SDK versions.
- Corrected Figure 11.7 CMU HFXO Control State Machine on page 314 to reflect startup timeout configuration from the STARTUPTI-MEOUT field of the CMU_HFXOTIMEOUTCTRL register.
- References to selecting a third clock output removed from 11.3.5 Clock Output on a Pin and 11.3.7 Clock Output on PRS because the CMU_CTRL register does not contain the CLKOUT2 bit field.
- Updated Table 10.2 EMU Energy Mode Overview on page 234 to reflect CSEN availability in EM3 when the ULFRCO is the LFBCLK source.
- · Added 35. FPUEH Floating Point Unit Exception Handler chapter.
- · Removed all references to RFSENSE.

### **Revision 1.2**

February, 2022

- Description of the Bank Switch Disable bit in Configuration Lock Word 1 improved in 7.3.2 Lock Bits (LB) Page Description.
- Note added to 7.3.2 Lock Bits (LB) Page Description explaining that a hard reset is required for changes to the lock bits to take
  effect.
- Added UG266 User's Guide reference in 7.3.4 Bootloader section.
- Note added to 7.3.12 Bank Switching Operation explaining that CLW1 bit 0 must previously be programmed to 0 to enable bank switching.
- 7.3.13.1 Read-While-Write updated to show the mapping of flash pages allocated to the lock bits, user data, and bootloader regions and their association with the two physical flash instances.
- Added description of VLP and ACMP startup behavior in 25.3.12 External Override Interface.

### **Revision 1.1**

April, 2020

- Add MODINFO and MODXOCAL registers to section 4.7
- · Add WS2 case to table 11.3
- · Add note about ADC SCANINPUTID issue to section 26.3.3.2

#### **Revision 1.0**

### March, 2018

- Figure 4.3 System Address Space With Peripheral Listing on page 47: Fixed to show all peripheral mappings.
- 7.5.20 MSC_BOOTLOADERCTRL Bootloader Read and Write Enable, Write Once Register: Corrected descriptions of BLWDIS and BLRDIS.
- 7.3.2 Lock Bits (LB) Page Description: Added details about ALW bit 31.
- 9.3.3 Power-On Reset (POR): Clarification of Power-On Reset supply connection (AVDD) and threshold (1.2V).
- · Added information about analog peripheral power connections and VDDX_ANA supply rail throughout document.
- Added information about IOVDD and AVDD restrictions on analog input signals throughout document.
- 10.3.11 Brown Out Detector (BOD): Included missing BOD details in paragraph.
- Table 10.2 EMU Energy Mode Overview on page 234: Added LESENSE row and footnote for GPIO Pin State Retention in EM4
  modes.
- 10.3.5.1 Bypass Mode: Added information on when bypass mode can be used and how to do so.
- 10.3.9.1 EM0/EM1 Voltage Scaling: Clarification of reset effects on voltage scaling operations in progress.
- 10.3.12 Voltage Monitor (VMON): Added note about VMON hystereis and riding/falling thresholds.
- 11. CMU Clock Management Unit: Removed erroneous information about DPLL.
- 11.3.2.4 HFXO Configuration: Clarified steady state timeout and state transition to ready.
- 11.3.2.5 LFXO Configuration: Added recommendations for GAIN setting.
- 15.3.1.3 Configurable PRS Logic: Clarified ANDNEXT and ORPREV behavior for first and last PRS channels.
- 15.3.2 Producers: Added more detail about GPIO producer source.
- 15.3.5 DMA Request on PRS: Fixed incorrect bit / register names and clarified signals for DMA are PRSRQE0 and PRSREQ1.
- 26.3.17 ADC Programming Model: Added note about changing to ASYNC clock mode with KEEPADCWARM.

### Revision 0.5

January 17th, 2017

Initial release.

# Appendix 1. Abbreviations

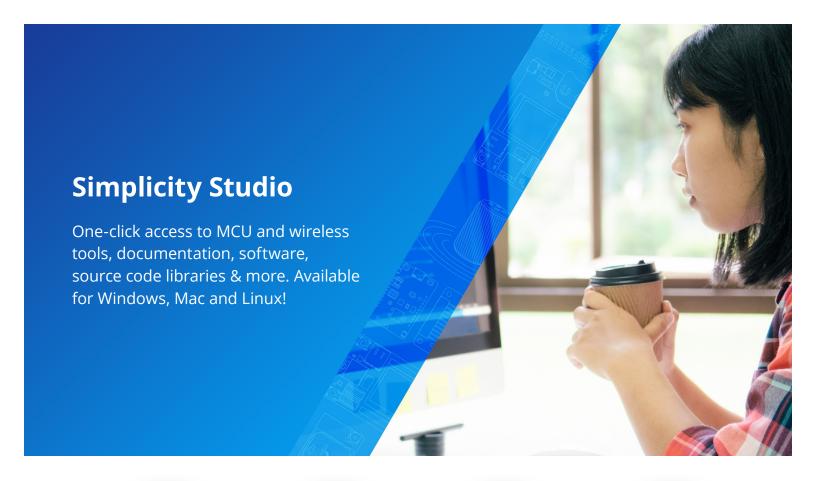

This section lists abbreviations used in this document.

Table 1.1. Abbreviations

Abbreviation	Description
ADC	Analog to Digital Converter
AES	Advanced Encryption Standard
AFC	Automatic Frequency Control
AGC	Automatic Gain Control
АНВ	AMBA Advanced High-performance Bus. AMBA is short for "Advanced Microcontroller Bus Architecture".
APB	AMBA Advanced Peripheral Bus. AMBA is short for "Advanced Microcontroller Bus Architecture".
APC	Automatic Power Control
ASK	Amplitude Shift Keying
BLE	Bluetooth Low Energy
BLE-LR	Bluetooth Low Energy Long Range
BR	Baud Rate
ВТ	Bandwidth Time product
BUFC	Buffer Controller
BW	Bandwidth
CBC	Cipher Block Chaining (AES mode of operation)
CBC-MAC	Cipher Block Chaining - Message Authentication Code (AES mode of operation)
CC	Compare / Capture
CCA	Clear Channel Assessment
CFB	Cipher Feedback (AES mode of operation)
CHF	Channel Filter
CLK	Clock
CM3	ARM Cortex-M3
CM4	ARM Cortex-M4
CMD	Command
CMU	Clock Management Unit
CRC	Cyclic Redundancy Check
CTR	Counter mode (AES mode of operation)
CTRL	Control
DBG	Debug
DC	Direct Current
DEC	Decimator
DEMOD	Demodulator

Abbreviation	Description
DSA	Detection of Signal Arrival
DSSS	Direct Sequence Spread Spectrum
ECB	Electronic Code Book (AES mode of operation)
EFR32	Wireless Gecko
EM	Energy Mode
EMU	Energy Management Unit
FEC	Forward Error Correction
FIR	Finite Impulse Response
FRC	Frame Controller
FSK	Frequency Shift Keying
GFSK	Gaussian Frequency Shift Keying
GMSK	Gaussian Minimum Shift Keying
GPIO	General Purpose Input / Output
HFRCO	High Frequency RC Oscillator
HFXO	High Frequency Crystal Oscillator
HW	Hardware
Hz	Hertz
IF	Intermediate Frequency
ISR	Interrupt Service Routine
LFRCO	Low Frequency RC Oscillator
LFXO	Low Frequency Crystal Oscillator
LNA	Low Noise Amplifier
LO	Local Oscillator
MOD	Modulator
MODEM	Modulator and Demodulator
MSK	Minimum Shift Keying
NRZ	Non Return to Zero
NVIC	Nested Vector Interrupt Controller
OFB	Output Feedback Mode (AES mode of operation)
OOK	On Off Keying
OQPSK	Offset Quadrature Phase Shift Keying
OSR	Over-Sampling Ratio
PA	Power Amplifier
PD	Power Down
PHY	Physical Layer
PROTIMER	Protocol Timer
PRS	Peripheral Reflex System

Abbreviation	Description
PWM	Pulse Width Modulation
RAC	Radio Controller
RAM	Random Access Memory
RF	Radio Frequency
RMU	Reset Management Unit
RSM	Radio State Machine
RSSI	Received Signal Strength Indicator
RTC	Real Time Counter
RX	Receive
SEQ	Radio Sequencer
SPI	Serial Peripheral Interface
SRC	Sample Rate Converter
STIMER	Sequencer Timer
SW	Software
SYNTH	Synthesizer
TX	Transmit
WOR	Wake On Radio
XTAL	Crystal

### Disclaimer

Silicon Labs intends to provide customers with the latest, accurate, and in-depth documentation of all peripherals and modules available for system and software implementers using or intending to use the Silicon Labs products. Characterization data, available modules and peripherals, memory sizes and memory addresses refer to each specific device, and "Typical" parameters provided can and do vary in different applications. Application examples described herein are for illustrative purposes only. Silicon Labs reserves the right to make changes without further notice to the product information, specifications, and descriptions herein, and does not give warranties as to the accuracy or completeness of the included information. Without prior notification, Silicon Labs may update product firmware during the manufacturing process for security or reliability reasons. Such changes will not alter the specifications or the performance of the product. Silicon Labs shall have no liability for the consequences of use of the information supplied in this document. This document does not imply or expressly grant any license to design or fabricate any integrated circuits. The products are not designed or authorized to be used within any FDA Class III devices, applications for which FDA premarket approval is required or Life Support Systems without the specific written consent of Silicon Labs. A "Life Support System" is any product or system intended to support or sustain life and/or health, which, if it fails, can be reasonably expected to result in weapons of mass destruction including (but not limited to) nuclear, biological or chemical weapons, or missiles capable of delivering such weapons. Silicon Labs products shall under no circumstances be used in weapons of mass destruction including (but not limited to) nuclear, biological or chemical weapons, or missiles capable of delivering such unauthorized applications. Note: This content may contain offensive terminology that is now obsolete. Silicon Labs is replacing these term
